FOUR DOLLARS A YEAR, SINGLE COPIES THIRTY-FIVE CENTS

(Continuing the California State Journal of Medicine)

INFANT FEEDING

THE PHYSICIAN HIMSELF is the most important factor in the successful feeding of infants.

BUT TWO OTHER FACTORS ENTER into the equation—

THE MOST IMPORTANT BEING the physician's control of the case;

AND NEXT IN IMPORTANCE the reliability of his infant diet materials.

MEAD'S INFANT DIET MATERIALS satisfy this last requirement. They are as reliable as it is possible for us to make them;

BUT THEIR INDIRECT INFLUENCE on the other requirement, the doctor's control over the feeding case, is even of greater value.

MEAD'S INFANT DIET MATERIALS are marketed to the laity only on the physician's prescription—No feeding directions accompany trade packages—The mother gets her information only from the doctor who changes the feedings from time to time to meet the nutritional requirements of the growing baby. *He therefore CONTROLS the case.*

THE PHYSICIAN can, with three MEAD diet materials, plus his skill and his control, satisfy the nutritional requirements of nearly all infants entrusted to his care.

MEAD'S DEXTRI-MALTOSE (carbohydrate) cow's milk and water, combined in proportions to suit the individual baby, meets successfully the requirements of most infants.

FOR OTHER INFANTS where additional carbohydrate is not indicated but additional protein is indicated (such as in Diarrhoea, Marasmus, Colic in breast-fed infants, etc.), the use of CASEC (protein) in the cow's milk modification gives gratifying results.

MEAD'S COD LIVER OIL, a standardized antirachitic agent of known potency, protects all infants, whether breast or bottle fed, from Rickets and can be given in such small doses as not to upset the fat proportion of the baby's diet.

Samples and literature describing these three diet materials

MEAD'S DEXTRI-MALTOSE • MEAD'S STANDARDIZED COD LIVER OIL

ADVERTISEMENTS

The Journal is published on the seventh of the month. Advertising copy must be received not later than the 15th of the month preceding issue. Advertising rates will be sent on request.

RESPONSIBILITY FOR STATEMENTS AND CONCLUSIONS IN ORIGINAL ARTICLES

Authors are responsible for all statements, conclusions and methods of presenting their subjects. These may or may not be in harmony with the views of the editorial staff. Furthermore, authors are largely responsible for the method of presenting their subjects. It is believed that the author's presentation determines to no small degree the value of his conclusions.

Therefore, both the author and the reader, in our opinion, are entitled to have the subject as presented as little disturbed as possible by the editors.

However, the right to reduce or reject any article is always reserved.

Doctor *Are You Reading* BETTER HEALTH?

OST newspapers, magazines and publications of every sort are now featuring alleged Health Education, Public Health, and even the practice of medicine by mail, as one of their functions. Of the few magazines that are producing worthwhile informative publicity in this field, BETTER HEALTH is the oldest. This magazine is owned and conducted by physicians and devoted entirely to improving the knowledge of the general public on matters pertaining to the promotion, conservation and protection of health; and it is one of the exceedingly small number presenting sound and authoritative health information of the same general type that the physician gives to his patients and friends. A copy should be on the table in your reception room at all times. Every physician, at least in the Western States, should be a subscriber to BETTER HEALTH Magazine. It needs your support for many and obvious reasons. If you are not a subscriber, please cut out the coupon and mail it at once. Suggest to your patients that they also subscribe.

To BETTER HEALTH, Balboa Building, San Francisco

Please send me BETTER HEALTH, the monthly magazine with the Daily Health Service, beginning with the January issue, 1925. Upon receipt of magazine and bill, I will send you \$3, payment in full, for one year's subscription.

Philosophy in Medicine—Under this title, Horst Oertel (Scientific Monthly) in a thoughtful and thought-stimulating essay, which should be read and pondered by every physician, considers "the sciences (including medicine) are children of philosophy or of that impulse which, for one or the other reason, forces the human mind to investigate the nature and connection of things. True enough, the immediate impetus of progress was often a very practical or protective one, but the result became at once the basis for generalization, and when the desired result was defeated, it became the source of speculation. . . . "There have been introduced by obliging bacteriologists and pathologists, in order to rapidly hitch their sciences to clinical medicine, all sorts of indefinite, largely hypothetical conceptions, such as 'virulence,' 'attenuated forms,' 'variability,' 'resistance,' 'strains' (which are distinguished by equally uncertain reactions), 'individual susceptibility,' 'carriers.' All these cover up deficient knowledge of causal relations, and are, at the best, heuristic. The calamity however, is that these words are construed by some as scientifically established connections of circumstances which may be regarded as finished entities and thus may be drawn upon to *explain* natural phenomena. . . . The bacteriological and especially immunological so-called explanations. What are they? Expression of causal relations or causal explanations? Not at all! Entirely metaphysical ideas! The definitions of 'immunity' itself, 'resistance,' 'defense,' 'purpose,' 'effort,' 'agglutinins,' 'precipitans,' 'lysins,' 'antibodies,' 'complement,' 'opsonins,' and so on, permeate in the shape of real entities, like a pre-Virchowian nightmare, the whole scientific texture of the infectious diseases. Now it might be urged, once more, that these are simply names or heuristic principles which are employed to cover defects, and as that they would demand a certain temporary standing. But actually that is not the case, for they are used to *explain* other unknown natural phenomena. . . . Can any one think of anything less scientific and more confused and muddling in reasoning? . . . What is worse, however, is that these purely personally assumed metaphysical attributes are now employed—it is really terrible to

acknowledge it in the twentieth century—to *explain* natural phenomena. Thus, we read that a 'toxin stimulates to the formation of an antibody,' and in one modern text-book on pathology I find 'inflammation' compared to the activities of a fire-brigade! Consider what all this means. An unknown assumed quality is employed to furnish us with scientific understanding of other unknown qualities; that is, one unknown explains or is intended to convey to our understanding another unknown, like Baron Munchhausen, who, having got stuck in a swamp, lifted himself by his own hair out of it. . . . This conception and acceptance of pathological entities, not as convenient names of categories, but as an expression of the independent nature of things which are dictated by teleological demands, still control in too large a measure the minds of the medical profession. Thus, through a deplorable lack of philosophical training, medical science stands at present a monstrous anomaly of causal, etiological, symptomatic and transcendent ideas. And thus it has been plunged into a hopeless muddle of definitions and classifications. . . . The science of pathology and medicine today are in bad shape, for the reason that their followers are still largely unscientific and not philosophically trained. Witness the grotesque modern attempts to trace complex *psychic phenomena* directly to the influence of *individual internal secretions* and thus to control them! Sciences atrophy and degenerate when they lose contact with philosophy. . . . The practitioner of medicine must be clear in his mind what is meant by logical cause and sequence, and what is an auxiliary conception which simply summarizes or interprets but can never explain. . . . What every practitioner of medicine really needs today more than anything else is sound critical judgment of values. . . . How is he to get judgment of values? There is only one answer. At present, as in the past, not by stuffing him with pseudo-science, or feeding him on practical dishes, cooked out of specially prepared scientific food, but through a philosophical consideration and understanding of *all* things which prepare him to follow and understand independently his own experience and that of others."

* Little Stories About Living Trusts

"My practice suffers"
—said the doctor.

"All in all, looking after my business affairs interferes with proper attention to my practice--it costs me money and is robbing my patients of time I should be devoting to them."

After poring over his investment ledger one morning, Dr. S—— had come to a Trust Company for advice as to how he might rid himself of some of the bothersome details attaching to his financial affairs, and insure for those affairs safe, economical management.

How he learned about the Safekeeping Account, its efficiency and flexibility, its remarkably low cost, is told in our new pamphlet—"There Aren't Enough Hours in the Day".

* Illustrative—Not Actual

American Mercury on Christian Scientists and Osteopaths—"The osteopaths and the Christian Scientists apparently have been employing their usual publicity methods upon Mr. H. L. Mencken, editor of the American Mercury. It did not work. Among his many trenchant sayings we note," says Illinois Medical Journal: "In every city wherein Christian Science flourishes its high priests and medicine men maintain a suave and persistent gentleman whose job it is to see that the local newspapers print nothing in contempt of the Eddyian magic. He is on watch day and night, seven days a week, and most of the managing editors of the land, having tasted his big stick at one time or another, are now exceedingly reluctant to stir him up. Within twelve hours after any reference to Christian Science gets into print that did not emanate from official quarters, he presents himself with a long typewritten rectification of its errors, and demands that it be printed. If the demand is refused, then the fun begins. The next day arrive several protests from writers who represent themselves to be old subscribers. The day following there are half a dozen telephone calls from local Babbitts, often eminent, all of whom explain carefully that they are not Eddyites themselves, but that it amazes and shocks them to see a reputable paper attacking and misrepresenting religion. The third day the managing editor is summoned to the office of the owner. So next day there is printed a long article, explaining solemnly that Mrs. Eddy was not a faith healer, that there is no connection whatever between Christian Science and the hocus-pocus of M. Coue, and that no Christian Science practitioner ever takes money for his assistance or pretends to do more than expound the authentic word and will of God—in other words, there appears the florid and effective press matter that the suave and persistent gentleman has had in his pocket all the time, and so the Only True Revelation gets another excellent free advertisement, and a few more neurotic women appear at the tabernacle the Sunday following, vice those lost to the New Thought, laparotomy or the embalmer during the week. I suspect that the osteopaths have borrowed the trick and are working it to excellent effect. They have made money in recent years, and so yearn for dignity and good repute. They no longer turn ice-wagon drivers into doctors in six months; they have begun to adopt professional airs. With this pretension goes better press work. But their fundamental pathological and therapeutic ideas, of course, remain nonsensical, and as such they will be represented, whenever they are mentioned at all, in the pages of this great moral journal. Whenever an osteopath grows intelligent he simply ceases to be an osteopath, and becomes an amateur physician of dubious equipment. So long as he is faithful to the teachings of Papa Still, the founder of the science, he remains an ignorant quack, and but little removed from his poor relation, the chiropractor. The pussyfoots of the new evangels may as well take warning forthwith that no conceivable bombardment of protests and demands, however cunningly disguised as neutral and virtuous, will ever penetrate to these chaste pages."

Sex Education as Old as Man—Sex education from earliest childhood is and always has been inevitable for man and animals. The how, when and what kind is the question. In a study of the early sex impressions of nearly a thousand college men, Doctor Exner (Social Hygiene) found that 63.9 per cent had received their first permanent sex impressions before the eleventh year. Eighty-seven and six-tenths per cent received them before the thirteenth year. It was found that 91.5 per cent of these college men had received their early sex impressions from *unwholesome sources*, that 80.5 per cent had received them from other boys, and only 4 per cent had received them from their parents.

To Know When We Do Not Know—The increasing frequency of doubtful clinical diagnoses and exploratory operations is not a detrimental reflection upon our ability as diagnosticians; it is, on the contrary, a sign of our diagnostic honesty and desire to put medicine upon an exact basis. We are beginning to know when we do not know. We refuse to guess and deceive ourselves.—William C. MacCarty, M. D. (Jr. Lab. and Clin. Med.).

A New and Larger Package of
ILETIN (INSULIN, LILLY)
At a slightly lower price

Iletin (Insulin, Lilly) is now supplied in containers of two sizes: 5 c.c. vials and 10 c.c. vials. Both the 5 c.c. and 10 c.c. vials bear the same designation: U-10, U-20 and U-40. To distinguish between the two sizes it will be necessary, for example, to order as U-10 - 5 c.c. vials or U-10 - 10 c.c. vials. In the absence of specifications, as to size package wanted, the 5 c.c. vials will be supplied.

The *concentration* in the 10 c. c. vial is the same as it is in the 5 c. c. vial bear-

ing the same designation. The 10 c.c. vials contain twice the quantity of material contained in the 5 c.c. vials and at a slightly lower price. This difference in price simply represents the difference in the cost of packaging 10 c.c. of Iletin (Insulin, Lilly) in one vial instead of two vials.

Your druggist can now supply you with the new 10 c.c. packages of Iletin (Insulin, Lilly).

In ordering, please specify vial size as well as unitage.

Twisted Colons and Inverted Commas—Described by "Volvulus" (Colorado Medicine) as follows: Symptomatology—The symptoms of this painful disease consist principally of attacks of abdominal colic of sudden onset. The syndrome may be encountered daily in any editorial office, Sundays and holidays included. Etiology—The cause of the disease can be unerringly traced to noxious material carelessly left in manuscripts by heedless authors. Such material is usually found in the following forms: (1) Ill-prepared copy marked "Dictated, but not read." (This noxious material frequently induces emesis.) (2) Sketchy notes used for a spoken address and not rewritten in manuscript form. (Emesis is often projectile in type.) (3) Twenty-page articles containing two pages of information. (Dyspnea and cyanosis.) (4) Crude abbreviations: Soda-bicarb, the Dr., P.S.P. test, R kidney, L.K., Sec'y., Ass'n., %, etc. (Vertigo and diplopia.) (5) Common names in capitals: Measles, Breakfast, Digitalis. (Opisthotonus and nystagmus.) (6) Profuse underlining, calling for italics, "black caps," and loud speakers. (Aphonia and laryngismus.) (7) Footnotes that should appear in the body of the manuscript. (Perspiration, chills.) (8) Left-hand spelling: Rockafellow Institute, edema, volumn, ilio-cecal, posteriorally, etc. (Tracheal edema.) (9) Illustrations not furnished with titles. (Petit mal.) (10) Single-spaced typewriting, which precludes correction of any of the aforementioned errors. (Visceroptosis and grand mal.) Treatment—The treatment of this grave and painful condition is chiefly prophylactic. There is need of more careful and considerate authorship. Fatal cases of this type of poisoning would occur less frequently if authors would seek and remove noxious material before releasing their manuscript for public consumption. In connection with such prophylaxis, a few "Suggestions to Authors" suggest themselves: (a) Send in your top

copy; not a smeary carbon. (b) Write on whole sheets, not half-sheets of paper. (c) Write your name on every page. (d) Furnish a title for each illustration, but do not write it across the face of the picture. (e) Make your references clear. Do not quote "Dr. Smith," but quote "Dr. Iota Magnus Smith." In giving references, do not conclude them with a penciled question mark. Do a little more work on the job. (f) In submitting a manuscript based on a paper read at a meeting, state in a footnote where and when the address was given. Thus: Read at the Annual Meeting of the Colorado State Medical Society, October 7, 8, 9, 1924. This footnote should appear at the bottom of the first page of the manuscript. (g) Conclude all manuscripts with a brief summary. (h) Do not plan to make the final draft of your paper on the printer's proof. Use the proof only to show printer's errors.

Iowa has State Circulating Medical Library—The earnest attention of those interested in improving medical and health facilities for everyone is invited to the news item about the Iowa Circulating Medical Library: "The Medical Department of the Iowa State Library is for the use of physicians all over the state. Books or periodicals will be furnished, direct or by mail, to anyone who asks for them. Bibliographies on special subjects will be prepared and available literature furnished. Any material which is not in the library will be borrowed from the Surgeon-General's Library at Washington, D. C., the borrower paying all transportation charges. Any physician who wishes to receive regularly any periodical material will be listed for as many journals as he desires, and they will be sent to him as they are received in the library. A period of loan on all books and periodicals is two weeks."

New Books and New Editions *for the new year*

LISTED below you will find some of the new books or new editions that have come to us recently. These are carried in stock and any of them may be had by calling or writing. In fact, any book in print, if we don't already carry it, will be sent for immediately, whether American or foreign.

Diseases of the Heart, <i>by Vaquez</i>	\$8.50
Practice of Pediatrics, <i>by Kerley & Graves</i>	9.00

The abuses and wrongs which exist within our profession are ours to correct: it is for us to maintain our high professional standards, to strive for loyalty and solidarity within our ranks; it is for us to give to the public the knowledge which will enable it to discriminate between the real and the false, to be guided by intelligence instead of by superstition; it is for us to curb and direct the well-intentioned but too often ill-advised social legislation, conceived in the brain of the lay theorist and passed by the catch-vote legislator as an inconsequential sop thrown to the public in lieu of vital measures which he deems politically inexpedient.

The usurpation by the federal government of health tasks which should be delegated to the several states is not only subversive of the principles of democratic government, but affords at best only an expensive and ineffective means of obtaining the desired results. Salvation to be of lasting value must come from within; salvation from without is always followed by backsliding. The clinic for any given community, which has been arranged at a distant center with little or no attempt to obtain the co-operation of the medical profession of that community, is foredoomed to failure, and its actual cost will be out of all proportion to its accomplishments.

The future of medicine in this state, in this country is in our hands. We need vision, determination, solidarity and the future is ours. In the science of medicine, we have achieved the incredible within the span of a short half century, we are entering an era of even greater achievements—we cannot foresee, we can only dream of the conquests of the next fifty years. It is only in the art of medicine that we have failed, in human contacts that we have fallen short. Such failure has been due to virtue rather than to vice—we have been so wholeheartedly dedicated to our profession that we have been blind to lesser, selfish interests.

A PLEASANT AND EFFECTIVE REMEDY
for
COUGHS and COLDS
CHRONIC BRONCHITIS
RESPIRATORY DISORDERS

A remedy which may be prescribed for its usefulness in combating bronchial affections and other disorders of the respiratory tract.

*Does not contain any narcotic

Now Then!—"In certain parts of the country when something startling happens or is about to happen, interested observers may be heard to exclaim: 'Now then!' It fits in many instances. We have small doubt that the colloquialism will spring at once to the lips of some ophthalmologists when they learn what optometrists are proposing to do with them in New York state," says the A. M. A. Bulletin. "According to the Optometric Weekly and the Optometrist and Optician, May 29, 1924, a resolution has been adopted by the Optometric Society of the city of New York, proposing to compel all physicians to pass examinations in optometry before they may undertake to refract and to fit glasses. A bulletin of the optometric society is quoted as follows: 'Medical exemption should be discontinued, because by exempting the physician from taking the state board optometry examinations we admit that optometry is a part of medicine. If optometry is not a part of medicine, why should the medical doctor be exempted? Since optometry became a law in this state, the M. D. has kept up a constant fight against us year in and year out. Why not fight fire with fire? Some men claim that if the M. D. is compelled to take a state board examination he will become our competitor—a foolish argument. What prevents him from becoming our competitor now? Is he not exempted to compete with us now? Isn't it easier for him this way? The harder you make it for the medical doctor to invade our field, the less competition we will have.' Now then! In an advertisement in the issue of the Optometric Weekly cited above, the following advice to optometrists is given: 'Optometry has passed the "glass-fitting" stage. Don't be a "spex-fitter" any longer. Assert your ability as a professional man and render service, as well as supply glasses.' Again—Now then!"

Faulty Food Factors and Atonic Constipation—The complete and proper nourishment of the body is gradually assuming a more important aspect. Food in the stomach is thought of as nourishment in the body, without the realization that it is merely in the alimentary canal.—Journal A. M. A.

January

The Month of All Beginnings

Our word January comes from Janus, the Roman God of All Beginnings.

Janus was two faced; one looked forward with youthful hope unafraid; the other look backward over the success and experience of the past.

The Doctor who has a 100 per cent efficiency Medical Protective Contract is likewise contented either in anticipation or retrospection.

Let the first of your good resolutions be, safety first, for your good name, practice, personal property and estate by amply fortifying yourself against your greatest hazard, your professional liability.

Anastomosis of the Recurrent Laryngeal Nerve With the Descendens Noni—C. H. Frazier, Philadelphia (Journal A. M. A., November 22, 1924), reports further on the effect of suturing the descendens hypoglossi to the recurrent laryngeal nerve. Twelve patients have been under his observation. In nine of these the paralysis of one or both vocal cords followed a thyroidectomy, in one a gunshot wound, and in one an attempt at suicide. One case was not of traumatic origin. Of this number, six patients have been operated on, two of them on both right and left nerves. Thus there were nine operations in all; once the recurrent nerve could not be found; in the remaining seven, a satisfactory suture was effected. The ninth was a neurolysis. In three cases already function is returning. The others have been operated on too recently to warrant a report. The indications for the operation up to the present time have been twofold: (1) To enable the patient to dispense with a tracheotomy tube, and (2) to restore normal phonation. The operation proposed for the relief of paralysis of the recurrent laryngeal nerve is comparable in principle to that designed to relieve paralysis of the facial nerve. In the latter instance, innervation is supplied by transfer of the central segment of an adjacent motor nerve, be it the spinal accessory, the hypoglossal or, as Frazier has recently employed, the descendens hypoglossi, to the peripheral segment of the facial nerve. The appropriate nerve for recurrent laryngeal paralysis is the descendens hypoglossi; first, because of its accessibility; secondly, because it is a purely motor nerve; thirdly, because in the physiologic sense the muscles supplied by the recurrent nerve and the ramus descendens hypoglossi are a part of the same apparatus, and lastly, because the descendens hypoglossi could be sacrificed without any material ill effect. A summary is given of the cases seen and subjected to operation. Five cases are reported in greater detail.

Unrest in College of Surgeons—The Journal of the Indiana State Medical Association opens a long editorial under the above heading: "There has been a growing unrest and a spirit of dissatisfaction within the ranks of the American College of Surgeons which finally ended in two petitions to the Board of Regents, signed by prominent surgeons from various parts of the country, asking for certain changes in policy and management. Among the principal complaints are the following: That too many men are admitted to Fellowship that do not meet the requirements as originally laid down by the College, and that the College should adopt more rigid tests as to character, training, and intelligence of candidates; that the membership includes men who have not the highest ideals because they are either fee-splitters or generally reputed to be paying commissions under one guise or another, and that the College has made no effort to clean house; that men who have been reported unfavorably by a State Committee on Credentials have been admitted, and that these men do not measure up to the original standard, and many of them are immature; that there has been too much proselytizing of members and that there is too much of a tendency to build up a large organization without enough attention to the character of the men composing it; that the members of the college are not sufficiently conversant with the financial affairs of the organization and are entitled to know more in detail concerning the receipts and expenditures; that there has been undue and distasteful publicity in connection with the clinical congress held each year."

By general dispensation, Christian Scientists patronize dentists and obstetricians, although in theory these forms of medical assistance are in no different class from internal medicine, and in the thorough-going application of the principle of the cult no "material" means should be used to accomplish any result, the application of fertilizer to the soil being as great a lapse from "divine mind" as the application of quinine or a porous plaster to the animal body.—Professor Knight Dunlap (Scientific Monthly).

Mary's Help Hospital and School of Nursing

145 GUERRERO ST., SAN FRANCISCO, CALIFORNIA

A General hospital of 150 beds, spacious, sunny, attractive rooms.

Operating room thoroughly equipped, all modern facilities.

Complete equipment of Pathological and X-Ray laboratories.

FOR IRRIGATIONS and
WET DRESSINGS

DIBROMIN

GERMICIDAL — NON-IRRITATING
CONVENIENT

Dibromin forms perfect solutions by the simple addition of water.

Dibromin is employed in aqueous solutions ranging in strength from 1:10,000 to 1:2500. Such solutions may be applied by continuous irrigation, as in the treatment of extensive wounds, ulcerations, etc.; and for infections of the urethra, bladder or uterus. Dilute solutions are suitable for use as mouth washes, and as collyria in eye infections. Indeed, in any case in which chlorinated antiseptics or antiseptic dyes can be utilized, Dibromin will be found to be more satisfactory because of its potency, stability, and its non-staining and non-irritating characteristics. Moreover, the ease and accuracy with which required solutions can be made up is not to be overlooked.

Dibromin is supplied in 6-grain capsules in bottles of 50 only, as a convenience for making extemporaneous solutions. One capsule makes a gallon of 1:10,000 solution.

DIBROMIN, containing 55.9 per cent of bromine, is a white, crystalline, practically odorless substance, soluble in water up to 4 per cent, insoluble in oils. It is stable in dry form, but dilute solutions (concentration less than 1:1000) slowly decompose.

Write for literature; inquiries from physicians are welcomed.

PARKE, DAVIS & COMPANY
DETROIT - MICHIGAN

DIBROMIN IS INCLUDED IN N. N. R. BY THE COUNCIL ON PHARMACY AND CHEMISTRY
OF THE AMERICAN MEDICAL ASSOCIATION

The Hartung Hospital Silent Call Signal System

SAFE ————— SILENT ————— SIMPLE

Calling Station No. 104

FULLY GUARANTEED TROUBLE PROOF

The calling station herewith illustrated shows one of the sixteen combinations that we have to offer.

This station consists of the control switch with ball chain, slip connector, pull cord and pear shaped pendant attached. A slight pull on the cord illuminates a red lamp over the door in the room visible to the patient, over the door in the corridor, a red pilot lamp in the diet kitchen and utility room, and the lamp in the annunciator which shows the number of the room calling. These lamps continue to burn until the call is answered and the control switch knob restored to the off position by the nurse.

The push and pull Emergency Switch is used by the nurse only when she finds the patient in a critical condition and needs immediate assistance. The nurse, pulling out the button of the Emergency Switch, illuminates a green lamp in the corridor over the door of the room, a green pilot light in the superintendent's office, at the nurses' station and wherever desired. This Emergency call is restored, when answered, by pressing the button of the switch which extinguishes all the green lights. If desired an audible buzzer may be connected to the emergency switch.

The duplex convenience outlet furnishes a connection for portable electric devices such as examination or reading lamp, electric fan, etc. Two appliances may be connected to this outlet at the same time.

Illustrated booklet and detailed information upon application.

The Services of our Engineers are at your disposal.

Heart Station

A laboratory for the investigation of Cardiac conditions.

As we are equipped with highly specialized apparatus, in particular an instrument for determining the exact angle in which the patient is being examined, we believe we are enabled to give the heart and especially the Aorta a more than ordinary accurate examination.

An outline of our routine examination is as follows:

- (I) a. History.
b. Complete Physical Examination.
c. Heart Function Tests.
d. Kidney Function Tests.
e. Vital Capacity, etc.
- (II) X-RAY EXAMINATION
a. Pictures in Frontal Position.
b. Pictures at various angles.
- (III) FLUOROSCOPIC EXAMINATION
a. Study of the comparative size and shape of the different Cardiac chambers.
b. Measurement of the Anterior-Posterior size of the heart, frequently the first part to show enlargement.
c. Orthodiagram and Cardiac Pattern—the latter to be used in checking up your own physical findings.
d. An attempt to judge the quality of the heart muscle and determine its probable efficiency and reserve power.
e. Careful measurement of the Ascending and Descending Aorta.
- (IV) ELECTROCARDIOGRAPHIC STUDY
Almost indispensable as a diagnostic aid in many Cardiac conditions.
- (V) METABOLISM TESTS, ETC.
In all cases a detailed and comprehensive report is furnished which will include diagnosis, prognosis and suggestions.
No stay in the hospital is required.
No single test or examination can be asked for.

When one surveys the field of infant-feeding, it is evident that almost all, if not all, progress in the art of infant-feeding has been empirical. We despise the influence of the grandmother in the feeding of the infant, but have derived many ideas from her and are still under her tutelage. To the present science has served merely to explain why empiricism moved in this or in that direction or to show that her steps have been taken on solid ground.—Edward A. Park, New York Journal Medicine.

A low estimate of the number of men employed in the United States in manufacturing industries alone today is placed by Everett at 10,000,000. Based on Army figures, the yearly time lost through venereal disease in this group of industries would be 6,893,800 days. Of course, the actual financial losses are not represented by these numbers, for time is lost through complications, such as gonorrheal rheumatism and various syphilitic conditions, decreasing the working activity and increasing the liability to accidents.—Venereal Disease Information, U. S. P. H. S.

Does the Georgia Doctor Need a Broker to Sell His Services to the Public?—"Briefly, and in business parlance," says the Journal of the Medical Association of Georgia, editorially, "the question is: Shall the medical profession vend its products directly to the consumer, or shall it sell them to a middleman or third party?" This question has assumed increasing importance since the endorsement of periodic examinations of the apparently healthy by the American Medical Association at the San Francisco meeting. Commercial organizations and institutions have used this endorsement to urge the public to apply to them for these examinations. These companies acting as jobbers buy the physician's services at one price and sell them to the public at another. Should the physician deal with the jobber, or should he sell his services directly to the consumer? and what is going to be the ultimate effect on the independence and the welfare of the physician as a result of thus dealing through a jobber or middleman? When a physician signs a contract with a commercial organization to make physical examinations of all persons sent to him by the organization for a price set by the organization, and allows that organization to make its own charge to the individuals examined for the services rendered by the physician, the physician is selling his independence to the jobber. These institutions have further invaded the field of the practice of medicine by the examination of policy-holders in life insurance companies. One of them now claims to make such examinations of policy-holders in thirty-nine companies. They pay the examining physician—skill and knowledge make the examination worth while—\$2.50, but sell the result of the examination to the insurance company for \$5. Furthermore, they contract to make examinations of groups of employees for industrial organizations at so much per head, sending examiners from the home office. We are long suffering and loathe to take any stand which is not for the best interest of the public. But is such practice for the public's best interest? Some of them claim to be altruistic and carry the names of many of our most prominent citizens on their literature, but how much has any one of them given for altruistic purposes

Your Financial Problems

Whether they be the purchase or sale of securities, adjustment of holdings for diversification, to secure greater safety or larger returns, or to overcome income tax difficulties, they can be more easily solved if you consult us. As specialists in securities we will be pleased to assist you at all times.

in Georgia? Does any member of this association know of a single instance? The local physician is best qualified to make examinations for the public. When he needs help in any particular field he is best qualified to know where to seek such help. We favor periodic examinations of both children and adults, but believe that such should be made by the family physician and the records kept by him. He is, furthermore, the best judge as to just what and how much information should be given the person examined."

Oridine—The calcium salt of the iodized fatty acids of cottonseed oil. It contains from 23 to 25 per cent of iodine in organic combination. Oridine acts in the system similarly to the inorganic iodides. The iodized fatty acid radicle of oridine is not decomposed in the stomach, but a part of the iodine is split off when it enters the intestine. The undecomposed portion is readily absorbed and, as in the case of other fats, it is largely deposited in the tissues where it is slowly split up. As with other iodized fats, the action of oridine is exerted more slowly than that of the inorganic iodides. Oridine is marketed in powder and as oridine tablets for the prophylaxis of goiter, containing oridine equivalent to iodine 0.01 gm. Eli Lilly & Co., Indianapolis.—Journal A. M. A.

The Education and Duties of Nurses Out of Proportion—"The proper work of the trained nurse does not contemplate that she is in a position of primary responsibility. Her duty is to care for patients' needs under the physician. If she is to do more—to assume the physician's function"—believes Doctor William Allen Pusey, President of the A. M. A., "she should take the medical course. The things she has to do are simple things. The work she has to do in ordinary service does not require a high school training nor three years of hospital training. It needs young women of character and intelligence, of a sense of responsibility and of elementary education. Given such a woman, and the time required to teach her in the hospital, the technic of the nursing craft is a small part of three years."

Putting Mother's Milk in Baby's Bottle

COW'S MILK contains a much higher percentage of casein than mother's milk because nature intended it for the powerful digestive ability of the calf.

On the other hand, mother's milk contains a lesser percentage of casein and a much higher percentage of lacto-albuminoid — nature's protective colloid which enables the delicate infant organisms to easily digest and assimilate all the nourishment.

When cow's milk is fed to the infant, modification is necessary to make it more nearly correspond to mother's milk.

First among the available colloids is pure, plain gelatine. (Zsigmondy, Z. Anal. Chem. 40, 1901.) When 1% of Knox Sparkling Gelatine, completely dissolved, is added to the prescribed milk formula, the curdling of the casein by the enzyme acids of the gastric juice is prevented, and the nourishment obtainable from the milk is increased by about 23%. It is just like putting mother's milk in the nursing bottle.

Here is the most approved method of modifying baby's milk with gelatine:

Soak for ten minutes one level tablespoonful of Knox Sparkling Gelatine in $\frac{1}{2}$ cup of cold milk taken from the baby's formula; cover while soaking; then place the cup in boiling water, stirring until gelatine is fully dissolved; add this dissolved gelatine to the regular formula.

For children and adults follow the same method in the proportion of $\frac{1}{2}$ teaspoonful of gelatine to a glass of milk. Because of its purity, it is essential to specify Knox Sparkling Gelatine.

A package of Knox Sparkling Gelatine, together with the physician's reference book of nutritional diets, will be sent free, upon request, if you will address the Charles B. Knox Gelatine Laboratories, 417 Knox Ave., Johnstown, N. Y.

(Continued on Page 31)

Ultex lenses are almost universally accepted as the most satisfactory bifocal. Being made entirely from a single piece of true ophthalmic glass, they have the appearance of an ordinary plain lens; while its construction and the care used in its manufacture eliminate the color spectrum so troublesome in all other bifocals.

If you would provide your patients with clear, comfortable vision at all angles, prescribe Punktals (a Bausch & Lomb product), whose optical properties are such that the image does not blur even though viewed through the rim or edge of the lens. Punktals are especially recommended for patients who must wear their glasses constantly.

For presbyopes, consider the advantages of Cross Trifocals. First this lens has a common center for both distant and reading portions, eliminating the "jump" in changing the vision between far and near objects. Second, an intermediate field of vision is provided for in such a practical way that we all wonder why it had not been thought of before. Ask for our little booklet telling all about Cross Trifocals.

Authorities agree, we believe, that the geometrical center of a lens should not always be used for the optical center. If prismatic errors are to be avoided the optical center should be that point in the lens through which the eyes are looking for the greater portion of time. In reading, the optical center should perhaps be two or three m/m below the geometrical center. Our workmen are careful to follow your directions on this, as on other points of your prescriptions. Also our equipment enables us to produce such work accurately at all times.

Successful Ophthalmologists

Never does the successful Ophthalmologist stop with a successful diagnosis. Neither is he content with writing the correct prescription. Final results depend too much on the ingredients of the remedy. And as he interests himself with the purity and therapeutic properties of pharmaceutical preparations, so likewise he will be certain that only materials of inherent quality are used in filling optical prescriptions.

The glasses prescribed must be made from Bausch & Lomb, Ultex, or Cross Trifocal lenses, into which exact ophthalmic corrections have been ground by skilled mechanics. There should be no guesswork with either diagnosis, prescription or remedy.

From among several optical Rx houses doing good work, an increasingly large number of successful refractionists are choosing ours as the most dependable. We will endeavor to serve you well, too.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

* ————— *

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.
2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.
3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.
4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.
5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

SPECIAL ARTICLE

SOME PRACTICAL SUGGESTIONS REGARDING TESTIMONY OF MEDICAL EXPERTS *

By JUDGE PAUL BURKS, Los Angeles**

THIS SUBJECT IS ONE OF GROWING IMPORTANCE TO COURTS, PHYSICIANS, ATTORNEYS, AND PARTICULARLY TO THE PUBLIC, IN THE INTERESTS OF THE INTELLIGENT AND HUMANE ADMINISTRATION OF JUSTICE.

THE PRESENT INEFFICIENT LAWS AND CUSTOMS UNDER WHICH MEDICO-LEGAL PROCEDURE IS CARRIED ON IS ABLY AND INTERESTINGLY ANALYZED BY THE LATE JUDGE BURKS OF LOS ANGELES. THE AUTHOR'S PAPER IS ABLY DISCUSSED BY DOCTORS ANDREW STEWART LOBINGIER OF LOS ANGELES AND WILLIAM C. WOODWARD, EXECUTIVE SECRETARY OF THE BUREAU OF LEGAL MEDICINE AND LEGISLATION OF THE A. M. A.

WE HAVE NO HESITANCY IN URGING NOT ONLY PHYSICIANS, BUT ATTORNEYS TO READ AND PONDER THESE DISCUSSIONS IN THE INTEREST OF THE GOOD NAMES OF TWO GREAT PROFESSIONS AND OF INDIVIDUAL ATTORNEYS AND PHYSICIANS WHOSE REPUTATIONS, AND THE GENERAL WELFARE OF AN IMPORTANT AND NECESSARY SERVICE, NOW SUFFER BY UNFORTUNATE PROCEDURES.

WE COMMEND A CAREFUL STUDY OF THESE DISCUSSIONS TO THE JUDGES OF OUR COURTS, WITH THE HOPE THAT INTEREST MAY BE AROUSED THAT WILL LEAD TO IMPROVED LAWS AND IMPROVED SERVICE TO SOCIETY.

JUDGE BURKS SAYS THAT: "ANOTHER DESIRABLE METHOD OF OBTAINING EXPERT TESTIMONY WOULD BE TO HAVE THE TRIAL JUDGE APPOINT THREE WELL-QUALIFIED EXPERTS. ONE MIGHT BE APPOINTED AT THE SUGGESTION OF EACH PARTY, AND THE THIRD AT HIS OWN DIRECTION OR BY THE TWO THUS APPOINTED, AND THEN THESE THREE COULD BE REQUIRED TO HEAR ALL OF THE TESTIMONY AND PRIVATELY EXAMINE SUCH WITNESSES OR PARTIES, AND PRESENT TO THE COURT, IN WRITING, A REPORT WHICH, AS TO THE FACTS FOUND, WOULD BE BINDING UPON THE JURY. REMUNERATION FOR THIS SERVICE COULD BE DIVIDED BETWEEN THE PARTIES TO THE ACTION, OR TAXED AS COSTS AS ARE JURY FEES."

WHY NOT ARRANGE A CONFERENCE BETWEEN REPRESENTATIVES OF THE MEDICAL ASSOCIATION, BAR ASSOCIATION; THE JUDGES AND A FEW OTHER LEADING ORGANIZATIONS, AND MAKE A SERIOUS EFFORT TO BETTER A SITUATION THAT NOW REFLECTS UPON MANY ELEMENTS OF SOCIETY AND, THEREFORE, UPON CIVILIZATION AS A WHOLE?—EDITOR.

SUBJECT defined and elucidated.

Distinction between advocacy of a cause and establishment of facts clarified.

Dangers and troubles of present method discussed.

Methods for improvement suggested.

DISCUSSION by Andrew Stewart Lobingier, M.D., Los Angeles, and William C. Woodward, Chicago.

EXPERIENCES with which some of your members are familiar are, primarily, responsible for my having been requested to make some "practical suggestions" respecting testimony of medical experts in judicial proceedings. Nothing which may be said is to be construed as a criticism of your profession, or of any of its members. The honor which you have bestowed upon me is appreciated, and evokes in me a sincere desire to be of service to you.

This is the day of specialists. Experts of all kinds are called upon, with constantly increasing frequency, as witnesses in both civil and criminal cases to assist courts and juries in investigating and determining questions of fact relating to subjects with which men, ordinarily, are not familiar. In many cases which are now presented to courts and juries, the evidence of one or more expert witnesses becomes a factor of determining importance in efforts to reach just conclusions.

In the play of King Henry VI (Act IV, Scene II), Shakespeare puts into the mouth of Dick, the butcher, an expression which is so short and so pointed as to render pardonable its reproduction in its

* Read before General Session of the Fifty-third Annual Session of California Medical Association, Los Angeles, May 15, 1924.

** We regret to announce the death of Judge Burks on October 9, 1924.

completeness. It reads: "The first thing we do, let's kill all the lawyers." The circumstance under which those of your profession are likely to re-echo this sentiment is when you leave the witness-stand, after having served as a medical expert.

Efforts to confound you which, too frequently, are put forth by lawyers inexperienced in trial work are amusing, and usually serve only to make the confusion of your ready terminology worse confounded. On those rare cases, however, when you are subjected to what our newspaper friends term "a gruelling cross-examination" by one skilled and experienced in the well-nigh-lost art of cross-examination and able to pierce your armor of technical expressions, then, friends, oh! then someone is apt to emerge from the fray resembling the proverbial "two-bits plus carfare."

HISTORY OF MEDICAL JURISPRUDENCE

One of the best definitions of "medical jurisprudence" to be found is that of Dr. T. R. Breck, one of its early and most eminent cultivators. He refers to it as:

"That *science* which applies the principles and practice of the different branches of medicine to the elucidation of doubtful questions in courts of justice."

The different branches alluded to in this old definition, doubtless, are chemistry, anatomy, physiology, pathology, etiology, hygiene and the practice of medicine, surgery and midwifery. To these there must, of course, now be added toxicology, psychology, roentgenology, and other specialties as they develop.

Not until the fifteenth century did the actual, practical study of analytical chemistry and of human anatomy progress far enough to impart to each of these departments of knowledge the character or dignity of a distinct branch of medical science.

In the history of the Jews, the Egyptians and the early Romans, are found items that may with fairness be said to belong to the domain of medical jurisprudence. Not, however, until the Code of Laws promulgated by George, Bishop of Bamberg, in 1507 and, more fully, in the "Caroline" Code by Emperor Charles V of Germany in 1552, do we find any real recognition by the law of the value of medical facts in legal proceedings. This code contained the first provision requiring medical men to appear in court as witnesses, and directed that their opinion should be taken in cases where death was alleged to have occurred by violence and suspicion of a criminal agency existed.

The nucleus from which sprang the French system of medical jurisprudence was the order of King Henry in 1606, requiring his chief surgeon to designate, in each large city or town, two surgeons who were required to examine and report on all wounded or murdered persons. At about the same time we begin to find in England recorded instances of the employment of medical witnesses in criminal trials.

In the trial for the murder of Jane Norkett in 1628, a body was disinterred for a second inquest thirty days after the first inquest had been held. The Coroner's jury at the first inquest returned a verdict of suicide. It was shown upon the trial that, when Jane Norkett's body was disinterred for the

second inquest, one of the persons accused of her murder touched the body, "whereupon the brow of the dead, which before was of a livid and carrion color, began to have a dew or gentle sweat arise on it which increased by degrees until the sweat ran down in drops on the face, the brow turned to a lively and fresh color and the deceased opened one of her eyes and shut it again; and this opening of the eye was done several times; she likewise thrust out the ring or marriage finger several times and pulled it in again, and the finger dropped blood on the grave."

The earliest works on medical jurisprudence worthy of special mention are those of Fidelis of Italy in 1598; Zaechus in 1621; Ambrose Paré, 1630; Deveaux, 1693; Bohn, 1702; and Fodere in 1796. During the seventeenth and eighteenth centuries a limited amount of instruction in medical jurisprudence seems to have been given in the Medical School of Edinburgh and in some of those on the continent of Europe.

The medical department of Columbia College of New York is entitled to the credit of establishing, in 1804, the first full professorship of medical jurisprudence in America, which was filled with much ability for many years by Dr. J. S. Stringham. Similar chairs were established in Louisville Medical College in 1812, occupied by Dr. Charles Caldwell; in the College of Physicians and Surgeons for the Western District of New York in 1815, filled by Dr. T. Romeyne Beck, and in Harvard Medical School in 1816, filled by Dr. Walter Channing; since then this branch has become recognized as a necessary part of the curriculum of all the more important medical schools, both in this country and in Europe.

Few, if any, state boards of medical examiners will now recognize as in good standing any institution which omits full instruction in this important branch. This is eminently proper when we consider that every practitioner of medicine is liable at any time to be hailed into court to give strictly medical testimony necessary, not only for the detection of crimes and the decision of questions of mental capacity, but also bearing on the public health of the various activities and industries of society and concerning the nature, extent and probable consequences of constantly recurring personal injuries which, in spite of all laws enacted and devices invented and rules of conduct promulgated, increase in frequency with the development of modern methods of travel, trade, and industry.

VALUE OF MEDICAL JURISPRUDENCE

The value of the application of chemical processes in detecting and determining the nature of poisons in cases of homicide and suicide, and in detecting adulterations and impurities in air, water, food products and drinks, for the prevention of frauds and for the protection of public health; the application of a thorough knowledge of anatomy and physiology as an aid in determining the nature, extent and probable consequences of wounds and personal injuries, whether homicidal, suicidal, or accidental; the application of the facts and principles constituting the physiology and pathology of the brain in the determination of questions regarding

mental competency, idiocy, and insanity are all so frequent and so generally acknowledged as to render unnecessary any illustrations of their incalculable worth and frequent use.

All concede the great value to men of your profession of a thorough knowledge of medical jurisprudence because upon *you* devolves the responsibility of occupying the witness-stand and imparting such facts and opinions as may enlighten courts and juries and facilitate the administration of justice. The equal importance, however, of the study of medical jurisprudence by lawyers and students of the law has been too long overlooked.

The lawyer does not find it necessary to go upon the stand in an effort to impart valuable medical knowledge to the court and jury. For that reason, he is apt to feel it unnecessary to master all the details of chemical analysis, causes of mental and physical diseases, and the probable consequences of acts of personal injury. He forgets that the important responsibility of deciding when, and what kind of, medical evidence is required in a given case rests upon him and that upon him devolves the work of eliciting such evidence from medical expert witnesses in such a manner as to insure its being understood by the court and by the jury. If he has not at least as much medical knowledge as is contained in our best works on medical jurisprudence, it is utterly impossible for a lawyer accurately to know the kind of medical expert testimony essential to proper enlightenment as to how so to frame his questions as to elicit from them those facts and opinions which are necessary to attain the ends of substantial justice and to avoid subjecting both himself and his witness to humiliation and embarrassment.

The average lawyer is poorly equipped to cope with the medical expert in his own field of inquiry because his research of medical authorities is rarely such as to fit him to undertake a task always delicate and often dangerous. Few attorneys are capable of examining medical experts. Fewer still are there who, should it become necessary, are capable of discrediting, with a jury, a well-informed witness of this kind. Any extended cross-examination along the line of such expert's theory, unless conducted with the utmost skill and assurance, is apt to prove disastrous by affording an opportunity for enlargement upon testimony already given and explanation of that which may have been overlooked or misunderstood by the jurors.

CAUSES OF DISSATISFACTION

As soon as the testimony of medical experts was recognized by the law, doctors commenced to disagree. As far back as the early part of the eighteenth century, we find reflections upon the merits of this kind of evidence equally as frank and outspoken as those frequently made by the bench, bar, and newspapers of today. An example of the contempt for expert testimony so often expressed by modern judges is found in the charge to the jury in the trial of Spencer Cowper, an Englishman of high position charged with the murder of Sarah Stout, a Quakeress, whose body was found one morning in a millstream. The evidence showed that Cowper was last seen with her the night before. The medical questions involved were most emphatically contro-

verted by physicians on both sides, and Baron Hattell, presiding, said:

"You have also heard what the doctors and surgeons said on the one side and the other concerning the swimming and sinking of dead bodies in the water; but I can find no certainty in it, and I leave it to your consideration. The doctors and surgeons have talked a great deal to this purpose and of the water going into the lungs or thorax; but unless you have more skill in anatomy than I you will not be much edified by it."

Some years later we find in the records of another criminal trial what must have been an early case of the now all-too-common defense of "brainstorm." In this case the curious result of the denial to the prisoner of the assistance of counsel in trials for felony was that Lord Ferrers, who was being tried, set up insanity as a defense and was obliged himself to examine the witnesses called in support of his plea.

There is probably no class of expert witness who is so prone to overindulge in a pedantic use of technicalities as is the physician or surgeon. This doubtless is due to the nature of his science. It is particularly true of the younger members of your profession. In an early report of a case of assault, a house surgeon testified:

"I discovered considerable ecchymosis under the left orbit, caused by extravasation of blood beneath the cuticle."

Baron Bramwell—"I suppose you mean the man had a black eye."

Scientific Witness—"Precisely, my lord."

Baron Bramwell—"Perhaps if you had said so in plain English these gentlemen would better understand you."

"Precisely, my lord," answered the learned surgeon, evidently delighted that the judge understood his meaning.

The foregoing would have been worthy of the young practitioner who described a suppression of perspiration as "an agglutination of the sebaceous follicles."

Tendencies thus indicated have shown some improvement. Instances, however, are still frequent where a medical expert—particularly if he is testifying before a jury—indulges in the use of technical and other expressions which the lay mind cannot possibly comprehend. The result is that court, counsel, and jury not only lose interest and fail utterly to comprehend what is being said, but also at times are made positively weary. The use of plain and equally effective words would have an opposite effect, would command interest and respect and promote the ends of justice.

In a recent case it became important to determine the length of plaintiff's leg as bearing upon the extent of personal injuries for which damages were sought. Defendant's counsel, upon cross-examination, asked plaintiff's medical expert from what point he had made the measurement to which he had previously testified. In the language of his calling, the expert replied: "From the anterior superior spinal process of the ilium." "A-h-h! My God!" exclaimed the attorney, overpowered by a jargon more mysterious than his own. After further ex-

amination, he succeeded in eliciting the fact that the place with the name "of learned strength and thundering sound" was the small point of bone on the side of the hip that can be felt with the fingers.

Experts of every kind have pet systems and theories by which they are prone to solve knotty questions presented to their art or science. They often do this in perfect innocence unless restrained by the watchfulness of court and counsel. Medical experts, unfortunately, are not exempt from this temptation and, under the prevailing custom, "with medical questions more doubtful, perplexing and complicated than the legal issue on trial, with masses of testimony confused and contradictory, a number of medical men in a cloud as to what has been proved and what has not, two or more lawyers who do not understand the physicians, it is not reasonable to expect that a jury, however sensible, could evolve order out of such chaos." It is not surprising that there should exist a growing desire not only among doctors and surgeons, but also among lawyers and judges to reform an altogether unsatisfactory condition.

After an experience of a lifetime at the bar and on the bench, the final judgment of Judge Campbell was that:

"Skilled witnesses come with such a bias on their minds to support the course on which they are embarked that hardly any weight should be given to their evidence."

Taylor, in his treatise on the "Law of Evidence," emphatically declares:

"Expert witnesses become so warped in their judgment by regarding the subject in one point of view, that, even when conscientiously disposed, *they are incapable* of expressing a candid opinion."

The unfortunate fact is that these opinions are so generally entertained and so often justified. Important cases frequently arise, however, in which the testimony of such witnesses must be reckoned with. It is now quite generally understood among lawyers that it is only by an ability properly to examine expert witnesses that jurors can be enlightened and enabled to arrive at a just estimate of the value of such testimony.

Much of the dissatisfaction with expert testimony, more especially that of medical experts, is due not so much to lack of honesty or candor in men of your profession as to the utter inability of lawyers properly to examine such witnesses or to appreciate the merits or demerits of statements which are honestly made, but clothed in words not easily understood by untrained ears.

We all know that honest opinions of different experts can be obtained upon opposite sides of the same question and that dishonest opinions may be obtained upon different sides of the same question. There is, however, a clear and clean-cut distinction between matters of scientific fact and mere matters of opinion.

When medical experts are called upon to establish certain facts which are not matters of opinion, it should be practically impossible for them to disagree.

When it comes to the province of mere opinion

we know too well that these same experts differ among themselves to an extent which causes but little credit to be given to mere expert opinions as such, whereas under any proper system they should be received with the utmost confidence.

The "medical expert" should, and generally does, go upon the stand in a fairly judicial frame of mind. The lawyer by his manner of propounding questions or by the exercise of many little persuasive arts incident to his calling, frequently, if not inevitably, leads him into "taking sides." He is surrounded by conditions which, to him, are entirely new, is confronted with verbiage that is strange, even if it be intelligible, and is more or less annoyed and flurried by his surroundings. Under these adverse circumstances he is confronted with the necessity of making a categorical answer to questions that are put to him, more especially in his cross-examination, which cannot be answered categorically. Too few lawyers realize that in a profession like yours—a science or an art like yours, if you prefer—it is often absolutely impossible to answer a question categorically without the risk of conveying to the court or jury, as the case may be, an absolutely erroneous impression. Then, at the close of a more or less lengthy examination, you are often subjected to further imposition in the shape of what lawyers are pleased to term a "hypothetical question."

THE HYPOTHETICAL QUESTION

One of the most glaring evils of medical expert testimony is the hypothetical question which has come to play so important a part in our trials of today. This is the most abominable form of evidence that was ever permitted to choke the mind or throttle the intelligence of a juror. The theory of such questions is that they embrace or express in a few words (sometimes a few thousand) *all* of the main features of the case under consideration—an accurate synopsis, if you please, of all the preceding testimony. They are supposed to be predicated upon *all* of the facts, or assumed facts, bearing upon the question, and no others, and the doctor or surgeon is asked to assume the truth of every fact incorporated in the question, and express to the jury his unqualified opinion and conclusions as an expert from the supposed facts.

In many (probably most) instances, the witness has not seen, much less examined, the patient concerning whose condition he is called upon to give sworn testimony, and the jury often take the answers of the witness as direct evidence of the existence of the fact itself. The hypothetical question itself does not afford as much cause for complaint as does the fact that such questions are too often so loosely framed as to present an aspect of the case entirely different from any which is justified by the testimony. In too many cases an expert who makes a direct and unqualified answer to such questions leaves an absolutely erroneous impression. This explains why so many experts have made answers to such questions which have elicited adverse criticism and affected their professional standing.

It is difficult for a lawyer to overcome the injurious effect of such a question. A method sometimes indulged in is abruptly to demand that the witness repeat in substance the question that he is about to

answer, and his efforts to recall and repeat the various stages of the usually long question which he is about to answer sometimes makes the dangers of such questions immediately apparent to the jurors.

Successfully to combat the effect of a skillfully prepared hypothetical question requires *knowledge*, *experience*, and *astuteness*, which the average lawyer does not possess. At times it is possible to determine what are those parts of the question upon which the witness places particular stress or to narrow the witness down to some particular factor, the truth of which may have been left in doubt by the previous testimony. It is for the unexpected examination of this kind, as well as for the sentence or *twist* in the question which serves as the foundation for the answer, that the medical expert should be prepared.

Many, perhaps all, of you have been obliged to listen to hypothetical questions so imperfectly constructed that they could not be answered negatively or affirmatively without liability of inculcating errors or necessitating lengthy and qualified explanations, and yet you have seen many such questions answered by "yes" or "no" without the slightest hesitation by one whose conscience is less elastic than is yours.

FALLACIES OF PROGNOSIS

There was a time when the manufacture or exaggeration of injuries in damage cases against corporation had assumed the proportion of a trade among certain lawyers and doctors with distorted ideas of ethics. Fortunately, this practice is now very rare. The fallacy of prognosis is apparent to lawyers and doctors whose duty it is to defend such actions. It is often interesting to watch the history of such a case after a substantial verdict has been awarded and paid over to the suffering and "permanently incapacitated" plaintiff.

You have all heard patients doomed to early dissolution solely on the strength of physical signs, and yet you have seen them live in a most contumacious and scientifically unexplainable manner apparently as long as they desired. The captain of a ship was dying of scurvy, but the crew mutinied and he postponed his dying, put down the mutiny, and is still living. An old lady was near her end after an injury. The doctors agreed that she could not possibly recover, but she became vexed because of a suggested change in her will; made up her mind not to die just then; ordered her carriage and was driven to the home of a relative twenty-five miles in the country, where she lived four years longer. Forty-three years ago it was my misfortune to be seriously injured by the carelessness of a coachman. Had my parents brought suit against the employer of the reckless driver, it would have been an easy matter to find a hundred of the most reputable physicians (had there been so many in Los Angeles at that early date) who would have testified conscientiously that the injured child could not possibly live to attain his majority; that if he did he would be permanently crippled.

With so much fallacy in honest prognostication it is not strange that there is considerable "faking" resorted to by those desiring to pick up some easy money. The honorable member of your profession

must be continually on his guard to avoid being imposed upon.

SUGGESTED REFORMS

Much of the dissatisfaction with medical expert testimony is due to the shortcomings of attorneys either in failing to understand the requirements of their case or, if they do understand, in being utterly unable to bring out, by well-directed examination, those facts and only those which have a direct bearing upon the particular question under consideration.

Effectively to examine a witness requires that a lawyer should possess at least an outline knowledge of the subject of his examination. It is certain that to construct a question (especially of a hypothetical character) with sufficient skill to elicit a direct and intelligible answer from a medical expert requires more knowledge than the average practitioner of law will take time to acquire. Lawyers possessing the necessary medical knowledge are too apt to want to "show off" before the expert and the jury. My view, therefore, is that, until some way can be devised of avoiding the present method of eliciting expert testimony, thorough knowledge of medical jurisprudence should constitute a most important part of the required education of every lawyer, and that this branch of study should constitute an important part of the curriculum of every school or college of law, as well as of medicine and surgery. It cannot be doubted that a large part of the confusion and lack of proper methods in introducing and eliciting medical evidence is due to the too general omission of this study as an essential qualification for admission to practice law. In direct line with the suggestion there appeared in the press, a few years since, a dispatch following:

"Medical Courses for Lawyers—An educational innovation has just been put into effect by the Medical College of Loyola University, a Jesuit institution, which offers a course in medicine to law students and attorneys. Recent sensational murder trials have shown the importance, it is alleged, of a knowledge of medicine to the lawyer.

"The course will deal solely with medical and surgical subjects which commonly come up in court trials. Special emphasis will be laid upon the various forms of insanity, but the lectures will also take up anatomy, histology, pathology, neurology, and toxicology.

"The course is offered with the aim in view of preparing attorneys for intelligently questioning medical men on the witness-stand when they are called as experts."

Even in the direct examination of witnesses concerning the nature, extent and probable consequences of personal injuries in both civil and criminal cases, an attorney who has omitted medical jurisprudence from his curriculum of study fails to ask the very questions which would elicit answers of the utmost importance. On the other hand, he frequently wastes much time in pressing questions which are utterly irrelevant or useless. The truth of this observation is borne out by the fact that one of your profession frequently sits beside the attorney in important medico-legal cases, evidently acting as assistant counsel by suggesting the necessary medical questions and references. If the service of the phy-

sician is confined to this it can be countenanced, even though it is not complimentary to the actual attorney. If, as often happens, he finally takes the stand to give expert testimony in the same case, he inflicts an injury on the character of his profession. The sole duty of a medical witness should be to state such facts and opinions as he believes to be true without fear or partiality, which is difficult, if not impossible, for him to do and at the same time act the part of assistant attorney.

STATUTORY REFORMS

In England and the United States the contesting parties select their own experts and pay them. Equally qualified experts thus appear on both sides and flatly contradict each other.

In France the court may order an investigation and report by experts whenever it deems it advisable. If the parties cannot agree upon at least three experts, the court appoints them.

In Germany, since 1870, after the issues are framed upon which expert testimony is sought, the parties may agree upon the experts, and the court appoints those agreed upon, but it may confine the parties to a given number of experts. Sometimes the court submits to the parties the names of a number of experts, and allows each side to strike off a certain number of them, and then appoints those remaining.

In Prussia it is said to have been the custom to appoint as experts a physician and surgeon for every county. In addition there is a medical college in each province to which an appeal lies if the experts disagree or the parties desire it.

A plan suggested in England and tested at Leeds was for medical men to refuse to testify unless before doing so they could meet in conference with the experts from the other side, and have an interchange of views; and it is stated that the result at Leeds was that medical witnesses were hardly ever cross-examined at all, and it was by no means uncommon to have them called on one side only. The plan is, of course, dependent upon a high standard of moral character and professional honor. The American physician and surgeon, as known to us, is generally qualified to satisfy these requirements.

The American Medical Association some years ago appointed a special committee to consider this question and report some plan. It is my understanding that such committee considered the advisability of having a board of experts of three or more chosen by the respective State Medical Associations, rather than elected by the people in the first instance or appointed by the Governor, who would be available to parties as expert witnesses upon the payment of a fee to the state, as we pay jury and trial fees, and who would act in conjunction with a medico-legal institute, such, for instance, as the State Laboratory of Hygiene is in chemistry today.

Another desirable method of obtaining reliable expert testimony would be to have the trial judge appoint three well-qualified experts. One might be appointed at the suggestion of each party, and the third at his own direction or by the two thus appointed; and then these three could be required to hear all of the testimony and privately examine such

witnesses or parties, and present to the court in writing a report which, as to the facts found, would be binding upon the jury. Remuneration for this service could be divided between the parties to the action, or taxed as costs as are jury fees.

It is only by the adoption of some such course that medical expert testimony can escape the adverse criticism to which it is now subjected.

The adoption in this country and in the various states of some plan such as above outlined, and the enactment thereof into proper laws, would do much to improve the means available to the medical expert of exercising the high prerogative of his science and assist in insuring righteousness and justice to all.

That a custom has become well established affords no sufficient excuse for its continuance, and if a new custom or method better fitted to present-day needs can be substituted with good results, it is your duty to assist in bringing this to pass.

The study of Medical Jurisprudence should form the most important link between the domain of law and that of medicine; it is the application of the facts and principles established in the more scientific departments of medicine in aid of legal processes for the support and protection of the highest interests of society, the detection of crimes, the preservation of public health, and the more exact administration of justice for all classes of society; it is the common ground upon which the members of the two professions meet for the common purpose of aiding each other in eliciting truth and in applying truth for the protection of the innocent, punishing the guilty, and in preventing or alleviating human suffering under the forms of the law.

The more thoroughly the members of both professions study this branch of human knowledge, the more harmonious will be their intercourse, each with the other, and the more successful will be their efforts to speed up the processes of the law and to promote the administration of substantial remedial justice.

DISCUSSION

Andrew Stewart Lobingier (Merritt Building, Los Angeles)—I listened to the reading of this scholarly address by Judge Burks with singular interest.

Fifteen years ago the Los Angeles Bar Association asked me to address them on this subject at a banquet given by the association to the Supreme Court of California. That was October 15, 1909. During the fifteen years following, under the authorization of the Councils of the Los Angeles County and the California Medical Associations and in collaboration with Mr. Oscar Mueller and Judge Frank Oster of the Los Angeles Bar Association, we have at various times prepared three bills governing expert testimony which were presented to the California legislature for passage. The first bill drafted was rejected by the legislature because it governed the giving of medical expert testimony only, and was considered to be class legislation. At the next meeting of the legislature the bill presented covered the giving of all expert testimony whether medical or from various other professions, as engineers, architects, chemists, etc. This bill passed the Upper House, but failed in the Lower. It was again presented in slightly modified form at the next meeting of the legislature, and was passed by both Houses, but vetoed by Governor Johnson. Not discouraged, Mr. Mueller and myself visited various cities and towns in the state—of course, at our own expense—making addresses before joint meetings of medical and bar associations, or wherever we could get an audience of physicians and lawyers to listen to us, in advocacy of this bill, which authorized the court to appoint its own expert, who by this appointment became an

officer of the court and hence was, as far as could be, divested of bias. The bill provided that counsel for the plaintiff or defendant could still have their own experts whose compensation and appearance they provided for; but the court's expert should examine the plaintiff and testify under direction of the court, though the witness was subject to cross-examination by counsel for either side. The compensation of the court's expert was provided for in the bill. The war came on, and after it one of us was absent from California for several years and nothing more has been done by us toward securing the passage of this legislation. I have learned from Governor Stephens that someone presented a bill governing the giving of expert testimony while he was the executive, and that at the request of several lawyers adverse to it, he had vetoed it, thinking it undesirable.

Whether this was a different bill from the one we have worked so long to have enacted, I am not prepared to say. At the next meeting of the legislature Mr. Mueller and I propose to present our bill again, in the hope it may have favorable consideration by the legislature and the executive. For at least ten or twelve years a number of our Los Angeles Judges of the Superior Court—conspicuously Judge Charles Monroe—have put in practice the calling of the court's expert in cases of doubt and difficulty and with apparently most satisfactory results. We have been privileged to contribute considerable time and assistance in getting the idea of the court's expert popularized in the local courts, and there is a very obvious increase here in the favor in which this method of giving expert evidence is being received.

I have faith that this exceptional address of Judge Burks will stimulate a genuine and widespread interest in this important subject. Since the vast increase in motor car accidents, the number of personal injury cases in our courts would in themselves demand some such assistance to expedite their adjudication.

William C. Woodward, M. D., Executive Secretary Bureau of Legal Medicine and Legislation of the American Medical Association, Chicago, Ill.—The judge, counsel, and an expert must come to an agreement in any case before an expert can get on the witness-stand. For such shortcomings as may appear thereafter, each must bear his part of the blame. For the correction of such defects as now exist in expert testimony generally, judges, lawyers, and the several groups from which expert witnesses are ordinarily drawn should co-operate. But before seeking correction through the enactment of new statutes, it should be definitely determined that existing laws are inadequate, and this seems to be peculiarly the function of bench and bar.

The primary responsibility of the judge is to determine whether expert testimony is needed, and if so, whether each particular witness offered as an expert witness is so qualified. In determining these questions the judge is guided by arguments of counsel, supplemented it may be, in the case of the qualifications of the proposed expert witness, by a preliminary examination in open court. Such examination is limited, however, to an inquiry into technical fitness and does not cover moral suitability. In arriving at his decision, the judge is bound by well-established principles of law. As between judge, counsel, and expert, it may be fairly said, I think, that the judge is the least responsible for such objectionable conditions as are now complained of.

The second collaborator in bringing about the appearance of the expert on the witness-stand is the lawyer. It is on his initiative that expert testimony is admitted. He selects the experts who are to testify for his side and induces the court to permit them to do so. He examines the experts offered by the opposite side, to disqualify them if unfit. He is free to determine whom he will, and whom he will not, present to the court as an expert witness, and in doing so he may take into consideration, not only the technical fitness of the prospective witness, but his moral fitness as well. If he will only refuse to bring into the court witnesses whom he knows, or might easily know, are willing and ready to quibble, to skim along the borders of truth, to evade, to conceal, and even to prevaricate, we shall hear less ridicule of expert witnesses, and expert testimony will be given its normal value. This much the lawyer can do without the enactment of any new law.

The third actor is the expert; but no expert can ever

get on the witness-stand unless some lawyer, with the judge's consent, puts him there. So much has been said concerning the expert himself that it is hardly necessary to add anything. That there are occasional experts willing to bear false witness to meet their employer's ends is probably true. Certainly, some witnesses are offered as experts by lawyers, and approved by judges, who could not so qualify among associates in their own professions. And there is a third class made up of men who may have the necessary technical qualifications and necessary integrity, but whose emotional reactions on the witness-stand lead them to unintentional, and it may be unconscious, exaggeration, or concealment. All three of these groups do harm, not only to their professions, but also to the cause of justice. Their conduct attracts public notice and brings condemnation on all, while the vast bulk of honest, competent expert testimony goes unnoticed.

As may be inferred on what has already been said, the problem of ridding the courts of dishonest and incompetent witnesses goes beyond a consideration of the witness himself, and involves counsel, and it may be the judge. The remedy most frequently suggested is, authorizing the appointment by the court of expert witnesses to represent, not the parties, but the court itself. Ordinarily, it is proposed that the testimony of such court experts supplement that of the witnesses testifying on behalf of the parties. A statute undertaking to regulate expert testimony in such manner was passed by the Michigan legislature some time ago, but has already been declared unconstitutional by the Supreme Court of the state (*People vs. Dickinson*, 164 Mich. 148, 129 N. W. 199). One of the strongest objections raised against it was that the testimony of witnesses acting on behalf of the judge would be given greater weight by the jury than the testimony of the witnesses offered by the parties, and that the parties might be thus deprived of a fair hearing.

But waiving any question as to the constitutionality of such legislation, it may be seriously questioned, I think, whether the situation would be materially improved simply by multiplying the number of experts, and arranging them in three groups, instead of two. If legislation is necessary, and if, in the hope of improving the situation, the court is to be vested by law with additional authority, possibly it should be authorized to appoint a competent expert to act on behalf of the judge, as a friend of the court, to cross-examine in open court the witnesses offered by both sides. The knowledge that an expert witness might be subjected to such cross-examination by an expert in his own line, equally or possibly even more competent than the witness himself, would be likely to go a long way toward deterring incompetent persons from assuming the role of expert witnesses, and would lead even the competent expert to a more thorough preparation of his testimony. Whether it would be practicable to procure men qualified to conduct such examinations, and particularly whether the ethics and clannishness of the particular professional group involved would not hamper such an expert examiner to an extent that might make the entire plan impracticable, are questions that can be answered only by experience.

The Trend Toward Federal Centralization is explained by Walter Thompson, Ph. D., in *The Annals Amer. Acad. Pol. and Soc. Science*, thus: "Reformers failing to realize their pet reforms through state action are prone to demand federal regulation. It is easier to convince Congress than to persuade forty-eight state legislatures, and the result is more far-reaching. Often reformers fail to realize that the reason state action has not been satisfactory is because the problem is a difficult one to cope with, and to try to realize the reform on a wider scale may increase this difficulty."

The oak tree produces a thousand acorns, from one of which a new tree may grow. We must have a thousand workers in the realm of the arts that one may rise to the plane of greatness. As to why we should foster art—there is but one answer and so obvious a reason that it is hardly worth the stating. Through beauty man's spirit is uplifted; to neglect it is to sink again to the depths from which mankind has risen.—Huger Elliott (*The Annals of American Academy of Political and Social Science*).

PRESIDENT'S ADDRESS—UTAH STATE MEDICAL SOCIETY, 1924

By J. R. MORRELL, M. D., Ogden, Utah

We cannot legislate ourselves into public esteem. We must each one perform a definite individual service, submerging any selfish interest for the common good, and establish a successful co-operative plan of action on the part of the profession in our state if we are to grow in public favor and confidence.

The cure for quackery in medicine lies in our rendering conscientious service with a desire only to do our full duty.

The average man is interested in the health of his farm animals and poultry, but in the family health often only after disease appears.

As long as we attempt to hinder each other in the work of popular health education, just so long will the confidence of the people be withheld from us.

Birth and death reports have been fairly well made, after years of effort, but our hearts are not in the work of vital statistics as they ought to be, and we alone can make a success of this important work.

Expert medical testimony is frequently asked of us and it is a common thing to find a number of men of good standing opposing each other on a case. Many of the most prominent men in our profession have found themselves in this position, and the public has come to regard expert medical testimony as a joke.

We cannot afford to be less efficient than we ought to be. We cannot do less than is expected of us in public service.

THERE are many tempting subjects inviting discussion in a paper of this kind, but I have tried to limit myself to a brief mention of a very few that I feel are of practical interest to our association. Through connection with a few of the official and volunteer health agencies in the state, and through participation in committee work within our organization and in association with outside committees, I have been rather strongly impressed with what I think are real problems that we have yet to solve before we take the place in public confidence that our profession is entitled to hold. These problems concern each individual vitally, and demand that he take a personal interest. The solution cannot be left to the officers of our society, because we cannot legislate ourselves into public esteem. We must each one perform a definite individual service, submerging any selfish interest for the common good, and establish a successful co-operative plan of action on the part of the profession in our state if we are to grow in public favor and confidence.

It is becoming more and more necessary that we have a broader outlook upon our profession than merely to use it as a means of making a living or the accumulation of money. A medical education is a broad, general training that should qualify a man for a much more useful life than he could have by the routine treatment of patients with no higher objective than the average practitioner has. It is a misfortune that a physician should be dependent for his living on fees derived from the treatment of the afflicted, because the temptation to commercialize, which is so strong, often leads one to do things that are not necessary, the results of which may not only be unfortunate, but disastrous. Failure in dealing with the health or life of an individual means much more than failure in commercial lines, and the responsibility is correspondingly greater, and one should not assume it unless he is prepared to jus-

tify the trust reposed in him by those who seek his help. A medical education automatically places a man on a pedestal and he becomes something more than a mere man, and if he proves unworthy of that position, not he alone suffers, but the profession of which he is a part is lowered in public esteem and favor because he has failed in his trust. The cure for quackery in medicine lies in our rendering conscientious service with a desire only to do our full duty. We have not only been negligent in our duty to the public, but we have been untrue to each other and have discredited each other in the eyes of the public. Insinuations that lead to suspicion or doubt of the integrity of another are so easy to leave, and praise or commendation is often so difficult that we fail to render a service that would mean much to our cause.

Medical education is expensive and a great part of the expense is borne by the public. Fees collected from students do not pay half the cost of their education, and the balance is paid by the public as taxes or comes from gratuities or endowments of various kinds. Because of the fact that the public has shared in the cost of our education, it is entitled to part of the benefit. We have learned something about preventive medicine, and it is our duty to see that that information reaches the people in order that it may be effective. We can in that way interest people who have confidence in us and at the same time render a co-operative service to the health agencies who are struggling to popularize health education. But we don't often interest ourselves in this work. We have numerous opportunities to instruct, and the majority of people are eager for the information, but we pass up the chance to render a service and they turn to the charlatans and the cults, who are all talkers, trained to teach their theories, and who never lose an opportunity to bring them before the people. We have always had the first chance and our indifference has resulted in a partial withdrawal of public confidence from our entire profession, and this in turn has made the work of health agencies difficult, as people feel that we are attempting to help our own cause and having nothing but a selfish interest in our health activities. If we were united and sincere in our efforts to teach health to the people; if we took the time to impress our patients with our personal interest in them; if we backed up the efforts of public health agencies in their educational work, instead of doing as we often do, ridiculing it, we would establish confidence and might go to any extent in public health education and legislation. The trend toward quackery, and the cults, is because of the sympathetic welcome they extend, with a personal appeal to each one. The large class of working people, whose help and co-operation we need most in public health work, we have to a great extent lost to the sympathetic cults, and our results will always be indifferent until we have re-established their confidence in us by better work on our part. We have scientific truth to offer, with the means of preventing serious illness, and many deaths, and yet because of jealousies, indifference and commercialism abnormally developed, we not only lose the opportunity to render a public service, but create a lack of con-

fidence in our motives. We teach public health in two ways, first, to the child through the school where he is taught health habits. This is the method that will be productive of the best results. But some physicians criticize this work or even antagonize it as a fad, or ridicule it as a useless procedure. The second method is by the teaching of adults, a much more difficult task, as many people are not interested in it. The average man is interested in the health of his farm animals and poultry, but in the family health often only after disease appears. During the recent goiter survey in this state, the only communication to the board of health asking for advice, was from a raiser of hogs who wanted to know how he might administer iodine to stamp out goiter in his herd. We can take a very active part in the education of the adult if we choose to do so, not only by our interest in teaching our patients, lecturing and writing on health subjects, but by giving our support to the work of the health agencies in the state. In the recent goiter survey, examinations of school children were refused by the board of education in one large district, on the advice of local physicians, who ridiculed the work and were able to influence the members of the board against the survey. From various other sources attacks were made on the survey, and doubt engendered in many communities as to the real purpose and intent of the work. As long as we attempt to hinder each other in the work of popular health education, just so long will the confidence of the people be withheld from us. Misunderstandings are often at the bottom of the troubles arising between health agencies, and between health agencies and the general profession. I would like to suggest that our committee on health and public instruction assume the role of intermediary and attempt to bring about co-operative work in all lines of public health activity in this state.

The public is willing and anxious to listen to the medical man whenever he is willing to talk, and he is usually received with enthusiasm by clubs, schools, parent-teachers' organizations and others before whom he might appear. The trouble is in getting him to do it, and while he is coming out of his trance the chiropractor, the traveling "fakir," and the itinerant specialist in diseases of men, women and children, have talked themselves into the confidence of the people and he cannot dislodge them.

The physician is not only the keeper of the health and therein of much of the happiness of his patients, but from an economic point of view he is one of the country's most valuable assets. When we realize this responsibility and organize for good, there is practically nothing that we cannot achieve in the highest interest of our art.

The erroneous belief held by many men that the practices of individual doctors will be interfered with by problems of health betterment which are promoted by lay and semi-medical welfare organizations or by the state, is responsible for much of the opposition of members of our profession. That this is a mistaken position, there can be no doubt, and the greater enlightenment that comes to the public, the better will be their ability to discriminate

in their choice of medical help which will ultimately react to our advantage.

We can support and uphold the laws and ordinances of our cities, state and nation, many of which have been enacted after careful study and consideration and have been more or less ineffective because of our indifference. We are expected to report cases of contagion to our local health authorities, to make reports of venereal diseases and of cases of tuberculosis, in order that the communities may be spared needless expense and perhaps many lives be saved. Public health workers checking up our interest in these activities find that we almost entirely ignore the reporting of tuberculosis and venereal cases and whole neighborhoods are exposed and often infected as a result of lack of supervision. Not 50 per cent of the reported deaths from tuberculosis for the last year had ever been called to the attention of the health boards prior to the signing of the death certificate.

Birth and death reports have been fairly well made, after years of effort, but our hearts are not in the work of vital statistics as they ought to be, and we alone can make a success of this important work. Let us not be the factor responsible for failure along this line, but make out our reports of contagious and infectious diseases, especially tuberculosis, as carefully and promptly as we do our reports of industrial accidents, from which we expect to collect a fee.

We have far to go still in the matter of co-operation with each other. As so strikingly told us last year by Doctor Landenberger, we are largely responsible for the troubles we have in the way of damage suits, by our insinuations of poor work or improper practice by another physician. This does not alone hold for personal damage suits, but also for suits against corporations, which are largely dependent for success upon adverse testimony rendered by men of our own profession. Those people with a grievance feel their way around until they find a physician of influence who is sympathetic to their desires, and soon a case is under way. The same attorneys handle most of these cases, and the poor deluded patient is the one who usually suffers, as in the end his compensation is usually less, the doctor is frequently discredited in the eyes of his profession, and the lawyers are the ones who have benefited financially. We should be extremely careful in our testimony in these cases, and professional co-operation and discussion of the merits of the case by the doctors concerned on each side would frequently result in a definite understanding and the testimony of all could be given according to the facts in the case, and we would not see the spectacle now so often enacted, of men violently opposing each other's testimony on the witness-stand and frequently making themselves ridiculous. These cases should be treated as private patients of another doctor, and instead of giving credence at once to any complaint they might have to make against the physician who treated them, make an effort to learn the facts, and talk the matter over with the doctor concerned in an effort to learn the true condition. Usually, if a conscientious effort is made, there is no case developed, and the results are better for all concerned,

as the outcome of a damage suit for personal injury is usually unsatisfactory for those engaging in it.

Expert medical testimony is frequently asked of us, and it is a common thing to find a number of men of good standing opposing each other on a case. Many of the most prominent men in our profession have found themselves in this position, and the public has come to regard expert medical testimony as a joke. They feel that it is just a matter of money and that the desired testimony can always be obtained if the price is right. The remedy for this condition is possible within our ranks if we are willing to co-operate with each other and work only for that which is right. Experts can discuss the merits of a case together, and if they do it with a desire to learn the facts, there is seldom any disagreement. If we do not remedy the condition ourselves, it is only a matter of time until courts will appoint medical experts and withdraw the privilege of employing experts at will.

The University of Utah is giving the first two years of the course in medicine, and is in need of the help of our association to make a success of that work. Last year, President Thomas appealed to us for help, asking that we develop a sympathy for the school and help to popularize it, instead of talking adversely of it. Many of us have not realized that we have a real medical school at the university, with capable men in charge of the departments, and I would advise every member of the association to visit the school and give it a careful inspection. You will find well-equipped laboratories and an abundance of material with which to work, and capable, well-trained men in charge of the work, most of them on full time. The school is a credit to our state, and we should give it our hearty support. Learn exactly what the school is, and then encourage men who are going into medicine to do their first two years' work there. Let us send our boys there as well, as we will then have a personal interest in it and will help to make it what it ought to be. Let us not lose the school to the state. President Thomas is determined to develop a real medical school or to abandon it. Let us co-operate with him and make a school of which we can all be proud.

These suggestions covering a number of fields of activity have appealed to me as our definite problems. We cannot afford to be less efficient than we ought to be. We cannot do less than is expected of us in public service. We owe certain obligations to our profession that we must assume. Lastly, we are indebted to ourselves most of all to play the part in our professional life that will make each one indispensable to our organization.

Eccles Building.

The Year's Record Estimated—Based upon past records and the probable degree of industrial activity, the United States Department of Labor has estimated that the 1924 accident record will show 21,232 deaths, 1728 workmen permanently and totally disabled, 105,629 permanent partial disabilities, and 2,324,829 disabled temporarily, a probable total of 2,543,418 accidents for the year. The actual and potential loss in work-days was estimated as totaling 227,169,970, while the wage loss, using an assumed wage of \$4.50 per day, reached the enormous figure of \$1,022,264,866.—California Safety News.

RICE WORKERS' DERMATITIS

By HARRY E. ALDERSON, M. D., AND AUBREY G. RAWLINS, A. B.

(From the Skin Clinic, Stanford University Medical School)

During the past few years there have appeared increasing numbers of cases of dermatitis known by those in the industry as "rice poisoning."

The dermatitis should be classed as occupational, whether due to dirt, fertilizers, water, mosquitoes, or other irritants to which men are exposed in their work.

DISCUSSION by Kendal P. Frost, Los Angeles; Charles E. Schoff, Sacramento; Charles E. von Geldern, Sacramento.

CALIFORNIA produced 5,469,600 bushels of rice during 1923 from an area of 106,000 acres in Butte, Colusa, Glenn, Sutter, and Yolo Counties, in the Sacramento Valley. Rice-farming, while comparatively new, has developed rapidly until it now constitutes one of the many well-established industries of the State. During the past few years there have appeared increasing numbers of cases of dermatitis known by those in the industry as "rice poisoning." Several cases have come before the State Industrial Accident Commission, and the matter has been referred by them to one of us (Alderson) for investigation. Several cases were studied and it was found that they were produced by lack of proper hygiene at work or at home, and that some of them were cases of seborrheic dermatitis with secondary pyogenic infection. Infected scratch-marks, resulting from bites of mosquitoes which were quite numerous in the rice fields, accounted for some cases. Of course, the dermatitis should be classed as occupational, whether due to dirt, fertilizers, water, mosquitoes, or other irritants to which the men are exposed in their work. Likewise, cases of eczema that develop under these same conditions in workers whose skins are more vulnerable as a result of seborrhea, anatomical defects, or constitutional conditions are certainly to be considered occupational.

A questionnaire was sent to the 130 odd physicians in the rice districts, asking for information regarding cases of rice dermatitis that they had observed. The following are typical of the replies received:

A. has had no cases. B. has had cases which he thinks were due to a dye or an oil in the sacks ("as some have appeared where the men have only handled sacks without being exposed to the rice"). C. has seen many cases. The patients usually had seborrheal skin, and hands, forearms, and legs were involved. D. thinks the disease due to local infection (staphylococcus) which enters through mosquito bites or abrasions in the skin. He states that he has had about three hundred cases. E. has had several cases. F. says that nearly always there are several cases in the rice-mill in his locality. G. (an eye specialist) reports many cases of conjunctivitis among rice workers. H. has seen several cases, but none this year. I. reports that, in his opinion, there is no such thing as a specific rice dermatitis, and that the workers are inclined to call every skin irritation "rice poisoning." He believes that dermatitis often results from handling sacks in the warehouse.

Judging from the replies, it seems that the so-called "rice poisoning" is decreasing in prevalence in

California. This might be due to the fact that there was less rice farming in 1923. The responses to our questionnaire would seem to indicate that a specific rice worker's dermatitis does not exist here, and this opinion for awhile was held by one of us. However, further investigation has convinced us that the reverse is true.

There is very little in the literature on the subject. Mantegazza describes a papulo-pustular dermatitis which involves the feet, legs, hands, and arms of large numbers of the workers in certain rice fields. It affects all ages and conditions more or less alike. Intense itching is a constant feature. The dermatosis subsides soon after removing the patient

1. Barley dust - Low power.

from his work. The author suggests the following possible etiological factors:

1. Predisposing causes: warmth of water, maceration, thinning of skin, alkalies, fertilizer, or other substances dissolved in the water.
2. Determining causes: thorns of a water plant ("najas minor").
3. Complicating causes: ordinary pyogenic organisms.

Sangiorgi describes a persistent itchy erythematous eruption which becomes oedematous papular and then pustular, involving the arms and legs only. He believes that constant immersion in water containing weeds, grasses, and also irritants in solution are the main etiological factors, and does not blame the rice plant itself.

In considering whether or not any given dermatitis is occupational, one should always bear in mind that there are many underlying factors that may increase the vulnerability of the skin. For instance, gastro-intestinal disturbances, indiscretions in diet, alcoholism disturbances of the endocrine gland system, idiosyncrasies for chemicals, food substances, unfavorable home environment, and focal infections. Also there are various local etiological factors, such as anatomical defects of the skin, seborrhea, hyperidrosis, diminished secretions of the skin, circulatory disturbances, irritating clothing, overzealous bathing, insufficient bathing, irritating soap, uncleanness, and hard water.

One of us (Rawlins) had considerable personal experience in this work while a student. From seeing a few cases, working in a rice warehouse, visiting the camps and talking with a large number of the workers, the impression was gained that the dermatitis is produced mainly by the irritating effects of the rice dust. Not a single case was observed (during the investigations carried through the summer) where water appeared to be the cause. All workers (including Rawlins) agreed that the rice dust itself was very irritating and caused severe itching. Barley dust has a similar effect, but the rice dust is more irritating.

In many of the rice workers' camps it was found that sanitary conditions were bad, the bathing facilities being quite deficient. Even where the conditions were good, however, often the workers failed to keep properly clean. It was noted that, even where the men kept very clean, there were numbers of cases of rice dermatitis. An important factor contributing to the general skin irritation is the constant presence of large numbers of mosquitoes in the rice fields. Another observation was that most of the soil in the rice districts is alkaline. This would tend to produce dryness of the skin, thus rendering it more susceptible to the effects of some irritants.

This dermatitis assumes different forms, varying with the individual. It appears to begin usually as

2. = Rice Dust - Low power.

an erythema accompanied by folliculitis with severe itching. Many of the lesions soon become pustular. Numerous excoriations from scratching appear. These often become secondarily infected. The sides of the fingers, flexor aspect of the wrists (thin epidermis), ankles, face, scalp, neck, and upper chest are the regions usually involved. Often there is conjunctivitis, which at times is quite severe. These are the areas, of course, on which most of the rice dust would be deposited. The wrist lesions are usually most aggravated, for here the rubbing of the sleeves or rubbing against the rice sacks are important factors. There are often cases where infected mosquito bites on exposed parts constitute the clinical picture.

For experimental purposes we obtained samples

of rice and rice dust from the various threshers, mills, and warehouses. We have tried to get patients with rice dermatitis for testing with these substances (offering them free hospital beds at Stanford), but so far none have appeared. This is greatly regretted, for such material would have produced valuable evidence, particularly on the subject of specific sensitization to rice. Protein skin tests will be applied as soon as proper material is available. We found one case among the workers who always had dermatitis and asthma when exposed to the grain dust. However, we tried out the materials on our own skins and on several of our clinic patients, utilizing regions where the epidermis was

3. Barley - High power of plant hair-

thin. We used the dry powder, aqueous and alcoholic emulsions of the same. They were rubbed into the skin and then gauze saturated with the material (dry and moist) was applied under adhesive plaster and left on for twenty-four hours. We did not test for protein sensitization. The usual result was a mild, slightly itchy erythema, which subsided in a day or so. It must be remembered, of course, that these conditions were different from those observed in the rice districts. The substance is on the skin of the rice workers constantly for many hours every day. The men, as a rule, are dirty and often irritated by swarms of mosquitoes. Clinical observations made in the rice districts, then, furnish the best, and we believe conclusive evidence that there is a specific "rice workers' dermatitis."

Microscopic examination of the dust shows, largely, a mass of plant hairs. Comparing the microscopic picture of rice dust and barley dust, using uniform preparations in cedar oil, there are about five times as many of these barbs in the rice as in the barley dust. (Note drawings.) This fact might help to explain why the rice dust is more irritating than the dust from other grains in the same vicinity.

Regarding the composition of rice, it was found that, unlike other grains, it contains a high percentage of silicon (about 16 per cent). This may account for the dust particles being more needle-like, and consequently irritating.

As far as we can learn, the *najas minor* plant (mentioned in Mantegazza's article) is not found in California. From the foregoing observations we feel justified in concluding that:

1. There is a specific rice workers' dermatitis, due

to the peculiarly irritating qualities of the rice grain. It has not yet been determined if protein sensitization is a factor in some cases.

2. There are also occupational dermatoses appearing on the skin of rice workers, as a result of scratched, infected mosquito bites, and dirt or both.

3. Unhygienic conditions in some of the camps and homes of the workers, as well as lack of personal cleanliness, account for some cases.

240 Stockton Street, San Francisco.

DISCUSSION

DR. KENDAL P. FROST (831 Pacific Mutual Building, Los Angeles)—Dr. Alderson's paper is a very stimulating one. There being no cultivation of rice in my section of the state, I have not had an opportunity to observe any of these cases. From the description I should be inclined to feel that the condition is not due to rice protein sensitivity, but rather to the mechanical irritation plus infection. Of course, there may be cases of rice sensitivity. In these one would anticipate a more eczematous syndrome.

CHARLES E. SCHOFF, M.D. (Farmers and Mechanics Bank Building, Sacramento)—I am pleased to have the opportunity of saying a few words relative to Dr. Alderson's paper, and it shows that he and Rawlins have spent considerable time upon this subject, which at one time was a much debated point, particularly with the State Industrial Accident Commission.

My experience with rice worker's dermatitis has been limited to five cases, three of which were definite dermatitis and two which proved, on investigation, to be a trichophyton in sack handlers of rice.

The cases were all referred to me after having been in progress some length of time, and were in individuals who were employed in the handling of "paddy rice" in the warehouse.

The skin manifestations varied from lesions confined to the hands, lower forearms and lower legs to a gen-

4. Rice - High power of plant hair

Rawlins

eralized involvement. There was nothing particularly peculiar to this type of skin irritation in its specific self, it being a papular, vesicular, traumatically excoriated, secondarily infected, diffuse, oedematous type of dermatitis, appearing first on the exposed surfaces and being confined there or spreading mechanically to the covered parts of the body.

The hygienic conditions surrounding these cases were good, two of them being men of families and homes, and the other housed in a hotel with facilities for body cleanliness and bed changes. Nor did I think that any of the cases presented a seborrheic type of a skin.

I merely mention these two facts to bring out the point that these cases developed in an atmosphere peculiar to

themselves; they persisted in that atmosphere and cleared up in due course of time when removed from the producing environment. It is of interest to note that one of the cases returned to work in the mill, and in a short time had a slight recurrence which necessitated his giving up that type of work, as he had been advised.

Another point of interest is that these cases do not develop in any other department of the mill other than in those who are handling paddy rice. I am informed from the mill management that clean rice workers, i. e., those employed in the polishing department, are free from such discomforts.

The trichophyton cases were peculiar, in that their lesion appeared practically at the same site although on opposite forearms about two inches above the flexure fold of the wrist, in truckmen who were handling rice—one employed in the field and the other in the warehouse.

The lesions were annular, about one and one-half inches in diameter, papular pustular, discrete folliculitis, the hairs showing a small spored ectothrix in both cases, with very few mycelium present.

Some work was attempted without results in an effort to determine if the animal habitue (cats and rodents) of the warehouse might have been the source, or if the mould on the sacks might have been responsible.

I quite agree with Dr. Alderson that there is a definite dermatitis produced in workers in rice. Whether this is due to a mechanical irritation from the dust, a chemical irritation or a protein sensitization still leaves a field for further investigation.

I question the protein sensitization, on the ground that if it were so it seems to me that we would see some of the cases originate in the polishing department of the rice mills, where the clean grain is handled entirely.

CHARLES E. VON GELDERN, M. D. (Forum Building, Sacramento, Calif.)—That the so-called rice workers' dermatitis is comparatively rare is shown by the scarcity of the literature and the fact that so few of these cases come under the care of industrial surgeons.

I fully agree with Dr. Alderson and Rawlins that the so-called rice workers' dermatitis is due to the irritating qualities of the rice grain which appear in the dust during the harvesting and in the milling. I saw, a number of years ago, a patient who had caulked a leaking feeder in one of the mills, and was subjected to dust and rice-hulls for a number of hours. His face, especially on the left side, was red, swollen and tender, with numerous small discrete papules. The itching was intense. The forearms were not affected to quite the same extent. The parts covered by clothing were not involved, which showed that the effect was a direct one.

A comparatively large number of rice workers have been sent to me for treatment for dermatoses. In most of these, the history did not show any relationship between their occupation and the disease. The most common affection was impetigo contagiosa. Two workers came from the same mill, at the same time, with a trichophyton infection. One of these men was employed in cutting out mouldy portions in sacks of rice which had been subjected to moisture. The other employee worked in the mill and did not come in contact with the first one, yet the lesions were similar in nature and location. At the time I made an investigation of the mill, but was unable to establish any definite relationship between the disease and the occupation. The manager of the mills had heard rumors regarding the cats which were said to be infected, but on investigation no disease was found among them.

On investigation, the various rumors and lay opinions were not substantiated, and at best the belief that the rice dust was the causative factor was merely suggestive.

It is, however, fairly certain, as shown by Alderson and Rawlins, that rice dust does produce a dermatitis in certain susceptible individuals, due to its abrasive action. It has not been shown, however, that such a dermatitis is specific, for, unless a clear history is obtained and the cases observed at an early stage, it is not possible to assert with any degree of certainty the cause of the skin manifestations.

Many of the dermatoses should be classed as industrial diseases, unless it can be definitely proved that the factors producing them are not connected with the occu-

pation. This is manifestly difficult, but it is only fair to the worker that he be given the benefit of the doubt.

DOCTOR ALDERSON (closing)—I wish to thank those discussing our paper for their valuable suggestions.

All available evidence is against there being specific sensitization to rice in these cases. Observers agree that the dermatitis is due rather to factors producing trauma or infection or both. As noted by Schoff and Von Geldern (who practice in the rice territory) cases are seen only among those exposed to rice before it is cleaned. If specific sensitization were a factor, cases would appear among those handling only the polished rice. Furthermore, as observed by Frost, the eruption would be more eczematous in character.

What One Health "Officer" Thinks of Baby Shows —"These baby shows make me sick. Think of hauling around a number of babies in the heat, dust and dirt that obtains at the usual county fair. Supposedly, this is done for the benefit of the babies. Actually, it is done because someone is making some money out of it, and so far as the poor babies are concerned it amounts to nothing. A fellow came in a few months ago. He said he was going to put on a baby show for one of the papers. I bluntly asked him where he would get his compensation, and he said he was an expert baby photographer. I told him, so far as the health department was concerned, there would be no sanction of his campaign, and so far as I was concerned, personally I was opposed to any such commercializing of child welfare. This fellow proved an expert liar. He went around and told other doctors and the visiting nurses I was in perfect agreement with his plans and he had everything set. I heard of this. I saw the editor of the paper and had a friendly talk with him, and gave him some ideas about baby contests he did not have. When the fellow returned to put on his campaign he found there was not a doctor in our city who would have anything to do with him. Of course, the nurses were ready, but the editor of the paper refused to go on with the thing, because he had become convinced that it was not really a child welfare proposition at all. So, we headed this one off. But later the — got mixed up with a combined beauty, better-baby-popularity contest. Those of us who are interested in pediatrics refused to have anything to do with it, but some of the other men spent some time at the county fair looking over the babies. What possible good can come to the babies in such hastily conducted examinations? I am off these things for life."—Indiana Medical Journal.

Wagner-Jauregg Treatment of Paresis—Doctor Jossmann, in reporting 100 patients treated by this method (Medical Standard), says that all stages of paralysis were treated by the method, and the result was that twenty-one patients were enabled to begin working again, although slight traces of paralysis were still present. Twenty-eight patients were able to resume work to a limited extent, the paralytic symptoms having undergone a considerable amelioration. In thirty-nine patients no improvement worth mentioning was noticeable, and twelve patients died during or in consequence of the treatment. Even in the improved cases slight disturbances of speech and irregularity of the pupils remained. The intellect did not entirely return to normal, and a lack of insight into the state of illness remained. Jossmann comes to the conclusion that, although it is still too soon for a final judgment to be passed, it has nevertheless been ascertained that, during the eighteen months in which the Wagner-Jauregg method has been available, improvement has taken place in about 50 per cent of the patients, especially in the early stages of the disease.

"For of Such"—The three realms of Fairyland, of Art, and of Nature constitute our being. The re-entry to fairyland, that land of wonder in which we never grow up out of that heaven which lies about us in our infancy, can be won by cultivating the friendship of children and by the study of the beauty of life in the land of dreams, out of which we may achieve when awake the realization of life's duty.—British Medical Journal.

CORONARY OCCLUSION AND MYOCARDIAL DEGENERATIONS

SOME CLINICAL AND PATHOLOGICAL CONSIDERATIONS

By WM. J. KERR, M. D., AND S. V. LARKEY, A. B.,
A. E. LARSEN, A. B.

(From the Department of Medicine, University of
California Medical School, San Francisco)

Disease should be more frequently recognized than it is.

Any male individual past 50 years of age (all fifteen of our patients were males) who, with or without previous history of cardiac symptoms presents a history of severe, agonizing, persisting pain in the chest or upper abdomen, accompanied by dyspnoea, unrelieved by rest, should be considered a probable sufferer from coronary disease.

Brief monographic consideration of all features of the disease.

CAREFULLY CONSIDERED DISCUSSION by James F. Churchill, San Diego; F. F. Gundrum, Sacramento; Thomas H. Kelly, San Francisco.

THERE is a striking increase in the number of deaths from the so-called degenerative diseases, due probably to the fact that more people are living into the age when these maladies tend to occur. With this increase, more emphasis is being placed on the early recognition and treatment of disorders of the cardiovascular system, associated with degenerative changes in the arteries. Coronary artery disease, with the resulting myocardial degeneration, is, therefore, of special interest. It is more common than earlier writers would have us believe.

The diagnosis of coronary occlusion, by thrombus, can be made in a considerable number of cases during life and suspected in a large number of cases where sudden death has occurred in individuals past 50 years of age. The condition should be more generally understood because, in its symptomatology, confusion with acute processes in the chest or abdomen may result. Needless and harmful abdominal operations are sometimes performed on patients with abdominal symptoms when the provocative disease process is in the heart or pericardium. A sufficiently large number of patients survive the first attacks of coronary artery occlusion to demand its recognition so that treatment may be adequate to promote the establishment of collateral circulation or the fibrosis of an infarcted area.

Our knowledge of the subject dates from the time of William Harvey, who described the symptoms and necropsy findings in a case where a large rupture of the left ventricle occurred. From then until the latter part of the nineteenth century a few case reports appeared in the literature, and many of the important points in regard to the condition were emphasized. In a monograph Robin and Nicolle, in 1895, gave an excellent review of rupture of the heart. More recently Dock, Huchard, Osler, Herrick and his co-workers, Gorham, and particularly Wearn, have clarified the clinical and pathological picture. Levine and Tranter reported two cases of infarction of the heart stimulating acute surgical abdominal conditions with necropsy findings. Crohn presented six cases of coronary disease where the abdominal symptoms and findings masked the true condition.

In two of these cases a previous history of peptic ulcer had been made. The electrocardiographic study of three patients with coronary artery disease with infarction by Kahn suggested the possibility of diagnosis by variations in the ventricular complex during the progress of the case. Reznikoff described a case with rupture of the left ventricular wall where stethoscopic evidence was obtained when the rupture took place. The sound was described as a "muffled, low-pitched, rushing rumble, louder in the expiratory phase."

Oberhelman, using a mercury injection method, showed a variation in the size, position and anastomosis of the coronary arteries in normal hearts and suggested that the time element was important in cases where occlusion occurred. This study confirmed the previous work of Herrick and Gross. Our studies with celloidin injection and corrosion preparations and bismuth sulphate injection preparations, which will be reported later, are in accord with previous observations on the coronary circulation.

Our study is based on fifteen cases observed during the past three years where both clinical and pathological data are available. An equal number of cases where the clinical histories were inadequate, or where necropsy findings were not obtained, are not included in this report. In a study of the data (Chart I) certain deductions may be drawn which, in the main, agree with previous work and are of importance in dealing with the condition.

ETIOLOGY

No outstanding etiological factors were noted. Eleven of the fifteen cases were in individuals after the fourth decade. Of those under 40 years of age, two showed subacute bacterial endocarditis which probably was responsible for infarction by embolism. In two patients, only 32 and 38 years of age, respectively, no etiological factors could be ascertained. Both individuals showed very extensive generalized arteriosclerosis. There was wide variation in occupation which is in agreement with the observations of Wearn. The preponderance of coronary disease among the male sex is shown by our series, all fifteen being observed in men. Heredity did not seem to play a role in our cases. In only one case was there a definite family history of heart disease. Infectious diseases were rarely observed in the previous histories. In four cases there was a history of rheumatism. Two of these showed subacute bacterial endocarditis with probable embolism to the coronary arteries with myocardial changes. In the other two no evidence of valvular heart disease was found at necropsy, although in one case pericardial adhesions were observed.

A history of lues, twenty-nine years before death, was obtained in one case and a positive blood Wassermann was recorded. Necropsy showed fibrosis of the interventricular septum and aneurysm of the left ventricular wall. In another case a weakly positive Wassermann was obtained, and necropsy showed a luetic aortitis in addition to a chronic fibrosis of the myocardium and mural thrombosis of the apices of both ventricles. Lues is not, therefore, a constant etiological factor, if our present methods

NO. 1

Injection-corrosion preparation of the coronary circulation of a human heart with coronary sclerosis.

NO. 2

Left ventricle of a human heart, showing extensive infarction with mural thrombi and an older process at the apex with thinning of the apical wall.

NO. 3

Human heart with occlusion of the left coronary and extensive infarction. Necrosis of the wall of the left ventricle is shown with a large irregular rupture of the myocardium. Sudden death after severe precordial pain and dyspnoea for four hours.

of clinical and pathological study are adequate to reveal end stages of this disease.

SYMPTOMATOLOGY

While there is considerable variation in the clinical picture of coronary disease, most of the features become intelligible when we consider the pathological changes in the heart and pericardium. We omit from our discussion the controversial points in regard to the causation of the attacks of pain in angina pectoris. In general the changes in the myocardium, in coronary disease, vary with the site and degree of the occlusion by atheroma, thrombosis, embolism, gummata or tumors; with the size of the occluded vessel; with the extent of the anastomosis in the area affected, which may vary normally and with advancing age of the individual; and with the time element in the process of occlusion. Small areas of the myocardium may become infarcted without any history or symptoms to indicate when the lesions were produced. Subjects with such lesions may show nothing on physical examination but enlargement of the heart. Occlusion of the descending branch of the left coronary artery, which is the most common lesion described, may lead to sudden death if the interruption of the circulation is abrupt, whereas if the obstruction is gradual, the infarcted area is usually smaller and the subject may survive. The process in the heart muscle may become necrotic with rupture of the wall, or organization may take place with resulting fibrosis or aneurysm of the left ventricular wall at or near the apex. Lesions of the septal branch, when acute or chronic, commonly result in serious disturbances of the conduction system. Occlusion above the septal branch lead to widespread pathology in the heart with a high immediate mortality. Other branches of the left coronary artery are less commonly involved, but may be

affected above or in association with those previously mentioned and produce less obvious symptomatology. The right coronary artery is occluded less often than the left except in luetic involvement of the base of the aorta, where there apparently is a preponderance of infarction of the right ventricular wall. Infarctions of the heart, if extensive enough to involve the endocardium, frequently lead to mural thrombi which, by embolism to the greater or lesser circulation, complicate the clinical picture accordingly. Similarly, processes in the myocardium, extending to the epicardium, frequently present the symptomatology of pericardial disease.

SUBJECTIVE SYMPTOMS

Pain is probably the most constant symptom which is met with in coronary disease. If it occurs after a history of angina pectoris the pain is described by the patient as entirely different in nature from that previously noted. It may occur without previous symptoms suggesting cardiac trouble. Its persistence and agonizing character are striking features and may be unrelieved by rest and large doses of morphine. The location of the pain varies widely, but is most commonly described as under the lower sternum or in the epigastrium. The pain may be referred to the left side of the neck, down the left arm, to the left sub-scapular region or to the upper part of the abdomen. In some cases there is a widespread distribution of the pain. Sensory disturbances of the skin may be noted over the precordium or over the painful areas. Dyspnoea persisting, in spite of rest, is a fairly constant feature. Gastro-intestinal symptoms, including upper abdominal pain, nausea, vomiting, pyrosis and flatulence, frequently direct the attention of the patient and physician to the abdomen. Mistaken diagnoses of perforated ulcer, gall-bladder disease, acute pancreatitis, and other

CHART I

Human heart, showing old area of infarction at the apex of the left ventricle with resulting fibrosis and aneurysmal dilatation.

diagnoses may result in needless and dangerous surgical procedures. (One of our patients was operated on for a suspected gall-bladder disease, and at necropsy was found to have coronary occlusion, with extensive infarction of the heart.) Vertigo and syncope associated with a failing myocardium or cardiac irregularities may be presenting symptoms. Emboli, lodging in the peripheral or pulmonary vessels, may be the first indication of coronary disease. Any or all of the above symptoms may be noted. However, many patients die suddenly without previous symptoms, and as such constitute a large percentage of sudden deaths. A small number of patients may give no history of cardiac disease, and at necropsy show fibrosis or aneurysm of the heart wall, indicating an old healed area of a previous infarction.

OBJECTIVE SYMPTOMS

There is a wide variation in the objective findings of patients suffering from coronary disease. In the more severe types the appearance of extreme suffering, prostration, ashen-gray appearance, feeble pulse, weak heart action, increased respiratory rate, passive congestion of the lungs, slight fever and leucocytosis make up the picture. The frequent accompaniment of tenderness and rigidity of the upper abdomen and distention complicate the picture and often mask the true nature of the disorder above the diaphragm. The enlargement of the liver, commonly of the left lobe, may simulate an abdominal mass or tumor of another nature. Libman describes sudden enlargement of the liver and cyanosis in association with right coronary occlusion. The roentgen ray findings in the stomach may give a constant but false picture of neoplasm or chronic ulcer such as occurred in one of our cases. Cardiac murmurs are common, but not characteristic. Previous rheumatic affections of the valves and luetic or sclerotic processes may present complicating diagnostic features. Subacute bacterial endocarditis may be the underlying process leading to embolism and infarc-

tion. Pericardial rubs are occasionally observed, and if noted are usually indicative of rather extensive infarction. Patients who survive one or more attacks of coronary occlusion may present the signs of congestive heart failure which often obscure the true nature of the underlying pathology. Cardiac irregularities, varying from extrasystoles, partial to complete heart block and ventricular tachycardia, are observed. Auricular fibrillation, auricular flutter are less often observed except with a failing myocardium. Electrocardiographic tracings show wide variations in the degree of block, shape of the Q-R-S complex and the T wave deviations, depending on the location of the lesion and its extent. Changes in the curves are noted with the varying clinical course. The blood pressure varies, but is usually lower than the readings for the respective age periods.

DIAGNOSIS

The diagnosis is made on a consideration of the above symptomatology. Few mistakes would be made if we keep in mind the possibility of coronary artery disease and myocardial degenerations in patients past 50 years of age who present upper abdominal symptoms.

CLINICAL COURSE

Sudden death is commonly observed. The usual duration is a few hours to a few days. Recurrent attacks may be noted over a period of weeks to years. Patients may rarely survive one or more attacks with fair or apparently normal cardiac function. Usually, however, the reserve force of the heart muscle is seriously impaired. Such patients must, therefore, lead a restricted physical and mental life. The outlook is gloomy, with the ever-present danger of subsequent extension of the process with sudden death. The prognosis should be guarded.

TREATMENT

The treatment is of greatest importance in the

group of patients who survive the first attack. A long period of complete rest is absolutely essential, free from physical and mental strain, to allow for fibrosis and anastomosis. Signs of myocardial insufficiency should be properly treated by depletion, limitation of fluids, diet with frequent, small feedings of easily digested, non-gas-producing food. Paracenteses may be necessary to remove embarrassing accumulations of fluid. Digitalis should be pushed to full effects during the stage of congestive heart failure, and small doses should be continued for a long time thereafter. A combination of digitalis, squill, and calomel is useful. Nitrites may be of value in controlling anginal pain, but morphine is usually required for the more persistent pain. Even large doses of morphine may fail to relieve the pain. Pyrosis and flatulence may be reduced by diet, free, regular, daily bowel movements, soda, prevention of air-swallowing, and other measures. This may be the most troublesome symptom to control and tax the ingenuity of the physician. Those patients who have outstanding abdominal complaints are difficult to convince that the diseased organ is the heart.

The acute fulminating cases present some different problems in therapy. Usually there is the picture simulating surgical shock. Rest is voluntarily accepted by the patient. There may, however, be great unrest and moving about in bed because of the severe pain. If nitrites give no relief—and usually they do not—opiates are indicated. Morphine may be given in increasing doses, and in many cases will promote rest and sleep. Caffein should be given in two to five grain doses intravenously or in larger doses subcutaneously. Distention should be relieved by stupes, gas enemata, a soft catheter in the rectum, and aromatic spirits of ammonia by mouth. Acute pulmonary edema, if present, should be treated by morphine and atropine. Venesection should be done if there is marked cyanosis, with enlargement of the liver, and the blood pressure is not too low.

PATHOLOGY

Almost without exception there is enlargement of the heart, the weight averaging from 400 to 500 grams. Atheroma of the coronary tree is a constant finding as an underlying factor responsible for changes in the myocardium. Occlusion takes place by gradual narrowing of the lumen at one or more places. Thrombus generally is found at the site of atheromatous processes and usually has caused a more sudden obstruction. However, calcareous plaques may be carried from the base of the aorta or portions of mural or valve thrombi may be dislodged from the left heart and lodge in the vessels, stopping the circulation to a portion of the ventricles. Gummata and tumors may rarely be the causative agents in restricting the coronary circulation. The resulting changes in the myocardium go through the various stages, leading eventually, if the patient lives, to fibrosis. At first there is local ischemia, which is smaller in area than the past supplied by the involved coronary, depending on the degree of anastomosis. Microscopic sections show an accumulation of fibrin and leucocytes and extravasation of erythrocytes. In some instances small miliary abscesses are noted and the infarcted area is soft and friable.

These features probably account for the fever and leucocytosis so frequently found. The presence of the leucocytes in such numbers indicates an older process than the duration of symptoms would indicate in many cases. The muscle fibers appear pale and swollen and the nuclei are piknotic. Fragmentation and further degeneration of muscle fibers may occur. As the process continues, granulation tissue forms, and the dead tissue is gradually replaced by firm fibrous tissue. A few muscle fibers may remain scattered through the scar tissue, but if the area involved is large the degenerated muscle tissue may be entirely replaced. The adherence of the parietal pericardium over the affected area may support the weakened ventricular wall or the diseased area may bulge outward, producing an aneurysm. Rupture of the ventricular wall with hemorrhage into the pericardial sac and death may take place during the stage of necrosis, but rarely later when fibrosis has occurred. Reinvolvements in adjacent or remote coronary branches reduplicate the original pathological picture.

Involvement of the pericardium accounts for the pericardial rub and pain in some cases. The severe constant pain over a wide distribution is not as yet fully explained, but much of the symptomatology can be interpreted as referred pain and spasm. The embolic phenomena are readily understood. The occurrence of irregularities and heart-block can be correlated with the pathological findings in many cases. The pathological findings, aside from those in the heart, are in general those of arterial degenerative disease in various organs, such as brain, kidneys and intestines, and the group of changes classified under the head of myocardial insufficiency.

SUMMARY

In a group of fifteen cases of coronary disease the clinical and pathological features have been studied. Our findings bear out the contentions of previous authors that coronary disease should be more generally recognized than it is. The symptomatology is confusing unless the underlying pathology is understood. Any male individual past 50 years of age (all fifteen of our patients were males) who with or without previous history of cardiac symptoms presents a history of severe, agonizing, persisting pain in the chest or upper abdomen, accompanied by dyspnoea, unrelieved by rest, should be considered a probable sufferer from coronary disease. The surgeon should be particularly on his guard in such patients with upper abdominal symptoms and signs. Extreme pallor and prostration, feeble pulse and heart action, low blood pressure, enlargement of the heart, passive congestion at the bases of the lungs, enlargement of the liver, slight fever and leucocytosis confirm the diagnosis. Such findings of murmurs, irregularities, embolic phenomena may help to locate the site of the process in the heart. The roentgen-ray examination may show a heart of unusual size or shape.

The course is variable, depending on many factors: namely, the causative agent, site of lesion, richness of anastomosis, and the time during which the occlusion takes place. The prognosis is poor and

death is frequently sudden. The treatment depends on the stage of the process.

University of California Hospital, San Francisco.

DISCUSSION

JAMES F. CHURCHILL, M. D. (Electric Building, San Diego, Calif.)—The group of cases in which there is an occlusion of a small branch of a coronary vessel and in which the patient frequently survives the attack is the one of chief clinical interest and importance. These cases are probably far more common than is suspected. Clinicians are making an increasing number of presumptive diagnoses of coronary occlusion to the great benefit of many of these patients. A careful pathological study of clinical material as presented in this paper is of great value to internists and general practitioners alike.

In this relatively mild group of cases the chief difficulty in differentiation is between obstruction and angina. In this differentiation I have come to rely chiefly on two points: first, the pain of angina is ordinarily relieved, at least temporarily, by vasodilators, while that of coronary occlusion is not; second, in coronary occlusion there is usually an immediate and marked fall in blood pressure, while in angina it is usually unchanged. It is true that there is often noted a fall in blood pressure some hours after repeated and severe anginal attacks, but it is not so abrupt nor so marked as in the other case. Therefore, it has become my habit, on seeing a patient with severe pain of anginal type, who obtains no relief from vasodilators and who shows a distinct drop in blood pressure, to make a presumptive diagnosis of coronary obstruction and to treat him accordingly. I believe the patient's chances of surviving the attack are increased by this policy.

The other cases for which we should ever be on the alert are those simulating upper abdominal lesions. The essayist has brought out this point and I only wish to emphasize it.

It is my observation that the majority of general practitioners are quite unfamiliar with coronary occlusion and, therefore, do not have in mind the possibility of that lesion in differential diagnosis. For that reason I would urge the presentation of papers on the subject before the County Societies.

F. F. GUNDRUM, M. D. (Capital National Bank Building, Sacramento, Calif.)—I find this excellent paper very timely. Our text-books say relatively little about coronary occlusion, and I believe most of us have usually considered it merely as a pathologic curiosity in some of the cases of sudden death. The clinical picture of sudden occlusion of a large coronary branch; the ashen-gray pallor; blue-purple lips; extreme prostration, sweating; weakness of voice and almost unbearable pain would be difficult to forget or confuse with any other condition. The picture, however, is not always so extreme. Whenever any patient, particularly if he be middle-aged, suddenly experiences a severe pain, cardiac, upper abdominal or brachial, after slight infection, overexercise or a large meal, and this pain is accompanied by great physical weakness, aggravated by exercise and unrelieved by vasodilator drug, such as whisky, nitroglycerin or amyl nitrite, coronary occlusion must be thought of as one of the first probabilities. It is of first consequence to the patient that this contingency be not overlooked. For any unnecessary manipulation, such as laparotomy or even passage of stomach tube for gastric juice examination or duodenal tube for investigation of the gall-bladder by the so-called Lyon technique, with its attendant retching, may be productive of a fatal mischief. Diagnosis is difficult, and physical signs much less helpful than careful history. These patients do not always die immediately after a blood vessel has been plugged, but occasionally live on, under a much reduced activity, for some months or even years. The treatment has already been outlined: it consists of morphine, small meals of food calculated to produce as little flatulence as possible, moderate limitation of fluid intake, attention to bowel evacuation and, most of all, sufficiently long bed

rest and stringent reduction of physical activity after leaving bed.

THOMAS HENSHAW KELLY, M. D. (240 Stockton Street, San Francisco)—I will not attempt to add anything to the excellent presentation of the pathology and symptomatology of coronary occlusion given in the present paper. I would, however, like to speak briefly of the importance of diagnosis and prognosis in this condition and to emphasize the importance of its early recognition.

We, as physicians, serve two purposes, the first that of curators of the sick, and the second that of prophets as to the outcome of nature's and our own efforts in behalf of our patients. It is in the exercise of this second function that we can often do great good, even though our first purpose is foredoomed to an unsuccessful issue.

Coronary occlusion is always a cataclysmic event, and we have not only an exceedingly ill patient upon our hands, but also a family stunned by the sudden terrible affliction of one of its members, and enormously distressed and perturbed by the possible or probable outcome of the attack. I do not need to picture for you the confusion, sorrow, and uncertainty existing in a home after one of its inmates has been visited by such a sudden and violent illness.

In a practice not to be qualified by the adjective "large," two patients have died of coronary occlusion within a year—one four, and the other five days after the onset of the disease. Both cases were recognized early, the suspicious finding being the persistence of the pain after the use of nitrites and ordinary doses of morphine. The patients were not informed of the probabilities, but their families were, and it was remarkable to note the calming effect upon them when certainty was substituted for doubt and they were warned of the inevitable end. We can bring a certain quiet and comfort to troubled hearts and minds when we can speak with certainty of the future, even though that future be fraught with grief. False hopes built upon false opinions lead only to greater stress and sorrow.

Thus it is that I wish to emphasize the need for us to know this lesion in all its phases, that we may not only safeguard our patients, but that we may be of real use to those so near to them and who at such times depend so much upon us and our opinions and advice.

DOCTOR KERR (closing)—The discussion by Doctors Churchill, Gundrum, and Kelly, emphasizes the frequency and importance of coronary disease in practice. If more thorough post-mortem examinations were done, I am sure this condition would be revealed in a great many cases where it is not now suspected, particularly in those cases where individuals die suddenly. In connection with the subject under discussion, it would be advisable to refer to two other papers which have been published since this one was written: Fredrick A. Willis and George E. Brown—Coronary Sclerosis: An Analysis of Eighty-Six Necropsies, *American Journal of Medical Sciences*, August, 1924; Hermon C. Gordinier—Coronary Arterial Occlusion: A Perfectly Definite Symptom-Complex; The Report of Thirteen Cases With One Autopsy, *American Journal of Medical Sciences*, August, 1924. These papers add a considerable number of new cases to the literature which is growing rapidly, and is of great value in such studies.

The Early Diagnosis of Joint Tuberculosis—Errors in diagnosis of joint tuberculosis are discussed by Alan DeForest Smith, New York (*Journal A. M. A.*, November 15, 1924). In the first two years of the disease, it always is difficult to make a positive diagnosis of tuberculosis of a joint. The only laboratory test that establishes the diagnosis is guinea-pig inoculation, and this is inconclusive when negative. The condition is obscured in many cases by immobilization before the diagnosis has been proved. The percentage of error in diagnosis of these conditions is high. The mistake of calling a non-tuberculous condition tuberculosis probably is just as frequent as the reverse. As a result of the large factor of error in diagnosis, much harm is done to the patients, and the statistics about the results of conservative treatment are misleading. Because of the extreme importance of being certain of the diagnosis, exploratory operation is indicated in all doubtful cases.

FOREIGN BODIES IN THE RESPIRATORY AND UPPER DIGESTIVE TRACTS*

By SIMON JESBERG, M. D., Los Angeles

Deliberate, careful study of the patient must be made. Symptoms caused by a foreign body depend on its location, size, shape and composition.

All foreign bodies cause suppuration eventually if they are not removed.

Team work is absolutely essential for successful bronchoscopy.

General anesthetics are rarely necessary.

ONE can hardly take up the discussion of modern bronchoscopy without the feeling that most of his words and ideas are borrowed from the works of Chevalier Jackson.

Many dangers and pitfalls surround the amateur bronchoscopist, as his problems are greater than those of one working in a clinic devoted solely to that work. He is often tempted into original modifications of technique—usually to his sorrow. His judgment is being constantly threatened by doctors and relatives of the patient, who demand hasty and immediate removal of the foreign body. It is often a difficult matter to convince them that there is no urgency and that a careful study of the case is much more essential than haste. It is difficult to maintain a trained team, without which consistently good work is impossible, and last but not least, the occasional case brought to him does not offer enough material to keep him in practice.

It is not intended that this paper shall cover completely the technique and problems of pre-oral endoscopy, but rather to present some of the most salient problems and adventures encountered in a series of forty cases. The distally lighted instruments have many advantages over those that are illuminated from reflected light in the handle, such as Breuning's. Visibility is much better, as the light is always on the field of operation and is not intercepted so much by the inserted forcep, as in handle-lighted instruments. Breuning said that actually seeing the action of the grasping forceps was more fancy than fact, and so it is with his instruments; but with Jackson tubes the forcep jaws are always more easily seen. This permits the development of technique and performance not possible when manipulations are largely guided by the sense of touch, as is necessary in Breuning tubes.

The element of luck is always present, but as one progresses he learns to depend not on that fickle lady for success, but rather upon following, rigidly, certain rules. Certain requirements are absolutely essential for the regularly successful handling of foreign body cases. They are:

Deliberate routine study of the case.

Team work.

Proper equipment.

Operative skill and technique.

Deliberate, careful study of the patient must be made. Doctors must be brought to realize that a foreign body is not an emergency, unless the larynx is obstructed, in which case, if suffocation is impending, a tracheotomy should be performed and then

time taken to study the situation properly. Fatal injury can easily be done by failure to appreciate the exact problems in a given case, such as location of the point of an open safety pin or the presence of sharp projections on an irregular foreign body. Failure to recognize such a situation is endangering a favorable outcome. Fatal perforation or rupture of the tissues can be avoided by proper appreciation and handling of the individual problem of each individual patient.

A definite history of entrance of the foreign body is usually given. Sometimes, however, the symptoms caused at the time the foreign body enters are too slight to attract attention, and it is only after secondary changes occur, such as lung suppuration or esophagitis, that attention is called to the condition.

Many physicians are slow to consider the possibility of a foreign body unless there is a history of its entrance, notwithstanding that symptoms are present which clearly indicate some unusual condition. Suspicion should be aroused in atypical instances of lung infection and an x-ray examination made. Even with a positive history, there are some who are slow to entertain the possibility of the presence of a foreign body.

Case No. 25 (Plates Nos. 1 and 2)—A 6-year-old girl aspirated a steel ball-bearing, which was allowed to remain in the lung nine months before discovery. Four days after aspirating the ball she developed pneumonia, which the physician failed to connect with the accident. He treated the patient, in consultation with other physicians, for nine months, during which time the child was subjected to rib resection and external drainage of the lung.

Case No. 28 (Plates Nos. 3, 4 and 5)—Carried a large nail in his right bronchus four months because his physician failed to associate his symptoms with the accident. The lung condition failing to clear up, he sent the patient to Arizona for climatic treatment, where an x-ray examination showed the nail.

Apparently more missionary work is still necessary to teach physicians that children do occasionally aspirate foreign bodies and that all atypical lung infections should be examined for this possibility.

Symptoms caused by a foreign body depend on its location, size, shape and composition. Thus a wide range of physical signs is possible. A foreign body in the larynx causes more or less aphonia and cough. In the case of a small foreign body, there is but little obstruction to the air passage. Subsequent edema, however, due to irritation by the intruder, may cause marked obstruction. Often cases with a laryngeal foreign body are diagnosed as croup. This is not surprising when we consider the frequent incidence of croup in young children.

Case No. 23—Had a safety pin in the hypopharynx for six weeks, during which time a variety of diagnoses were under consideration by the pediatric service of a large general hospital. It was only after curiosity was aroused to see what was causing the laryngeal edema that a laryngologist was called in and the foreign body located.

Case No. 30—Had a fragment of walnut shell in the hypopharynx for eight weeks. Even with a positive history of swallowing nut shells, he was under

* Presented to the Section on Eye, Ear, Nose, and Throat at the Fifty-third Annual Session of the California Medical Association, Los Angeles, 1924.

Plate No. 1, Case No. 25—Steel ball-bearing in left bronchus nine months.

Plate No. 2, Case 25—Pathology in lung four years after removal of ball-bearing. Clinically, the child is in good health except for expectoration of thick pus. She requires weekly bronchoscopic aspiration to maintain this condition of health. As soon as lung aspirations are discontinued septic symptoms begin. Postural treatment has been tried with no benefit.

the case of several men before a laryngeal examination was made.

Case No. 5—A 2-year-old baby was practically moribund when first seen by a laryngologist. He had been sick six weeks. A small piece of cancellous bone was found in the larynx. This patient died several hours after removal of the foreign body.

In the trachea, a foreign body causes coughing, particularly when it is moved about by the respiratory air blasts. With a stethoscope over the sternum, the movement of the foreign body can be heard. During forcible expiration, such as coughing, a thud is heard as the foreign body strikes the closed glottis. Tracheal thud was observed in case No. 32, caused by a sunflower seed in the trachea. A foreign body usually does not long remain in the trachea, for, if its size permits, it enters a bronchus and finally travels down as far in the tracheo-bronchial tree as possible. Inflammatory changes in the respiratory tract vary greatly, according to the nature of the foreign body and the degree of obstruction. Certain vegetable substances set up a violent reaction in a few hours. Peanuts and beans are particularly certain to do this. Metallic and wooden bodies usually cause but little reaction for a long time.

All foreign bodies cause suppuration eventually if they are not removed. Swelling of the mucosa about the foreign body aids in obstructing drainage of that part of the lung, which in time results in suppuration. When a bronchus is completely obstructed, atelectasis results. Air trapping occurs as a result of a partially occluded bronchus; i. e., either by a foreign body alone or else by swelling of the mucosa; the lumen is occluded completely during expiration, than during inspiration; the bronchus dilates slightly, permitting air to enter the lung past the obstruction. This results in emphysema of that part of the lung; displaces the neighboring structures; the diaphragm

downward and the mediastinal contents to opposite side. This air-trapping is well shown in a radiograph and is a most valuable aid in the detection of non-opaque foreign bodies.

Case No. 35 (Plates Nos. 6 and 7)—A peanut in the right bronchus. This is clearly shown. Radiographs are taken at the end of inspiration and at the end of expiration. The first shows emphysema of both lungs, the second emphysema of the air-trapped lung only, with the diaphragm depressed on that side and the mediastinal contents dislocated to unaffected side.

As suppuration results below an obstructed bronchus, clinical signs of pneumonia, with fever, rapid pulse, rapid respiration and cough are manifested. The breath has a foetid odor and there is profuse expectoration of foul pus. If drainage is not established by removal of the foreign body, tissue destruction results, forming a lung abscess. It is surprising how nature may heal such an abscess after the foreign body is removed.

In case No. 28 (Plate No. 5)—Four months after removal of the nail, the x-ray shows no remnant of lung suppuration. However, these lung suppurations do not always get well spontaneously. In case No. 25 (Plate No. 2) a ball-bearing in the left lung nine months, immediate improvement began after removal of the foreign body, and apparently complete recovery of the lung suppuration occurred in a few months. However, after one year's time, following a cold, suppuration again became active and the patient is still under treatment requiring weekly bronchoscopic aspiration.

A 2-year-old Mexican boy had a lung abscess drained externally. During course of treatment of his chest wound he coughed up a fragment of a walnut. He was discharged from the hospital as cured three months later. Two years later he was

Plate No. 3, Case 28—Nail in right bronchus four months. Note lung suppuration.

Plate No. 4, Case 28—Taken twenty-four hours after removal of nail.

Plate No. 5, Case 28—Taken six months after removal of nail. Note spontaneous recovery of lung suppuration.

under our observation, with extensive lung suppuration, and in spite of repeated bronchoscopic treatments he gradually became worse. The end result of this case is not known for the reason that he passed from my observation and treatments.

Foreign bodies in the esophagus, if they are smooth, and not causing complete obstruction, such as metal discs, may be tolerated for a long period of time with but slight symptoms. Usually there is some difficulty in swallowing solids. If the esophagus is completely occluded, the diagnosis is easily established. Sharp or irregular objects cause injury to the mucosa and inflammation within a short time.

When esophagitis develops, the mucosa is swollen and lumen contains pus which often has a foul odor. Swallowing is very difficult or impossible; pain is extreme; fever and general prostration are marked. Danger of mediastinal infection is impending. Perforation of the esophagus by sharp bodies is not infre-

quent. If perforation occurs in the cervical esophagus, a neck infection results which usually requires external drainage. Mediastinal infection, resulting either from extension of the neck infection or from a perforation in the lower part of the esophagus, has an extremely high mortality. Three cases of this series were suffering with acute esophagitis, each due to a small bone in the esophagus. All of these had swollen, tender necks, temperature about 102 degrees, and a septic appearance. In addition to the removal of the foreign body, the necks of two of these patients were drained externally. One was drained externally without ever finding the foreign body; the third case had only removal of the foreign body, without external drainage. All three recovered. These are cases No. 3, No. 7 and No. 11 respectively.

The x-ray is of the greatest help in the diagnosis of foreign bodies. No patient should be operated upon without first having had proper x-ray study. If the

Plate No. 6 and 7, Case No. 35—Peanut in the right bronchus, No. 6 shows air trapping in the right lung, decreased density of the right lung, depression of the right dome of the diaphragm, displacement of the mediastinal contents to the left.

No. 7, taken twenty-four hours after removal of the peanut, shows lung restored to normal.

foreign body is not opaque, the x-ray will be inclined to show a pathological picture indicating the location of the intruder. If the foreign body is opaque, plates taken in different planes show its exact shape and relation to the structures. At least one plate should be taken in a plane showing the longest dimension of the foreign body. Plate No. 8 shows a safety pin in the larynx. The antero-posterior view looks like a closed pin; the lateral plate shows it open, the point below the arytenoids and stuck in the tissue. With this knowledge, it was easy to remove the pin by first freeing the point. Had no x-ray been taken, the situation could not have been recognized, as the keeper end of the pin alone was visible. Traction on the keeper end of the pin could only have succeeded in imbedding the point deeper.

Non-opaque foreign bodies in the esophagus can often be demonstrated with an opaque meal. First: By a filling defect when the esophagus is filled by the opaque meal. Second: Retention of barium about the margins of the foreign body, outlining it after the rest of the barium has passed on.

Team work is absolutely essential for successful bronchoscopy. The most skilled bronchoscopist can not do his work unless he has trained helpers. It is the one who holds the head that has the really important job, and he must perform his work accurately. Failure to recognize this necessity almost always results in failure to introduce the tubes. This is the greatest obstacle encountered by an amateur team, and can be overcome only by development of team work through practice. The person who hands the instruments to the operator must be trained exactly in his duties, as a slight break in his technique may lose a golden moment of opportunity for the operator and turn success into failure.

A third helper is necessary to hold the shoulders down, thereby steadying the patient and permitting the head holder to extend the head properly. Operative skill and technique are acquired by practice only. Cadavers are not good material upon which to gain experience because the greatest difficulties encountered are not anatomical ones, but rather the movements of living tissues. Lung suppuration cases requiring frequent treatments are splendid material to keep one in practice. Case No. 25 (the lung supuration following a ball-bearing in the lung) has been bronchoscoped at almost weekly intervals for three years. Cases of bronchiectasis are not difficult to find and will appreciate bronchoscopic treatment.

When a foreign body is diagnosed it is of great aid to reproduce the object as nearly as possible; insert it in a rubber tube in the same position as it is in the patient and practice its removal with the selected instruments.

General anesthetics are rarely necessary. They are indicated more often by those less certain of their technique and skill, or where adequate assistance is not available. The more team work and technique are perfected, the less general anesthesia is necessary. Jackson uses no anesthetic nor analgesic in young children. I saw him perform forty-two consecutive endoscopic examinations and treatments without using a general anesthetic. In older children and adults he uses cocaine locally. I use butyn in 2 per cent and 5 per cent solutions in all cases. Butyn has

Plate No. 8, Case No. 22—Safety pin in larynx. With endoscopic view the keeper end alone could be seen. The position of the point was concealed. With information obtained from this radiograph the removal was easily and safely accomplished.

been used by me more than 300 times with but one toxic reaction. This occurred in a 4-year-old child that had had the drug used many times before. On this occasion a double dose was given through a misunderstanding. About 4 cc. of 5 per cent butyn was injected into the larynx and trachea. Fifteen minutes later he became cyanotic, frothed at the mouth and lost consciousness; there were several convulsions—the whole phenomenon closely resembling an epileptic fit. Recovery occurred quickly, just as it does in epilepsy. Butyn has been used several times since on this patient without any ill effect.

REPORT OF FORTY CASES OF FOREIGN BODY

Case 1—William W., male, 24 years. History: Three hours after aspirating pin. Now feels pricking in throat. Indirect inspection shows pin transversely fixed behind epiglottis, point stuck in right side of larynx. Diagnosis: Pin in larynx. Result: Removed with curved forceps, using laryngeal mirror. Indirect method. No anesthetic. August 1, 1922. Recovery.

Case 2—L. L., female, 15 years. History: Five hours before aspirated pin. Indirect inspection shows F. B. in right pyriform sinus. Diagnosis: Pin in larynx. Result: Removed with alligator forceps through Jackson's laryngoscope. No anesthetic, trendelenberg position. Time 10 seconds. June 7, 1923. Recovery.

Case 3—Elizabeth N., female, 11 years. History: Twenty-four hours before swallowed pin. X-ray showed F. B. in left pyriform sinus. Sent to Los Angeles from Calexico; x-ray here shows the pin on right side. Seen by indirect examination. Diagnosis: Pin in right pyriform sinus. Result: Ether anesthetic, Jackson laryngoscope, patient vomited, pin found after prolonged search in epipharynx. Removed. Recovery. June 9, 1920.

Case 4—Betty, female, 15 months, three days ago while playing in fireplace choked; some fragments of wood were removed by the mother from the mouth. Croupy cough and noisy breathing since. No cyanosis. X-ray negative. Diagnosis: Piece of wood in larynx. Course and result: Jackson laryngoscope, no anesthetic. Grasped with alligator forceps, rotated and removed. Kept in hospital twenty-four hours. December 4, 1923. Recovery.

Case 5—Baby F., male, 2 years. Hoarse six weeks, croupy cough with high fever two weeks, marked dyspnea last twenty-four hours. X-ray shows large thymus, otherwise negative, W. B. C. 24,000, temperature 103, respiration 32, pulse 140. Urine shows acetone. Child exhausted. Diagnosis: Bone in larynx. Course and result: Without anesthesia, Jackson laryngoscope and 4 mm. tube, laryngeal edema, small cancellous bone found in

glottis, removed F. B., trachea explored, breathing easier, six hours later collapsed, tracheotomy by intern, died one hour later. December 24, 1922. Died.

Case 6—Mrs. C. H., female, 35 years. Four days before, while eating chicken, felt sharp prick in throat; swallowing painful since; neck swollen twenty-four hours. Unable to swallow. Temperature 102; pulse 112. X-ray shows small shadow below cricoid level. Diagnosis: Chicken bone in esophagus; perforation; neck infection. Course and result: Ether, Breuning tubes and forceps. Intense swelling of esophagus; lumen contains foul pus. Bone two inches below cricoid on posterior wall, transverse, right end penetrates wall. Grasped and removed. Neck opened, external drain inserted to esophagus. Normal in four days. August 20, 1919. Recovery.

Case 7—William B., male 24 years. May 18, 1923. Felt bone swallowed while eating fish. Pricking on swallowing since. Indirect inspection negative. Refuses x-ray May 21. Still feels F. B. X-ray refused. May 22, chill, neck swelling. Painful swallowing. X-rays taken—negative for foreign body. Temperature 100, pulse 104, respiration 22. Neck on left swollen and tender. Diagnosis: Fish bone perforating the esophagus. Neck infection. Course and result: May 22, Butyn 5 per cent. Jackson Ant. Commisure speculum used to explore upper esophagus; also used esophageal speculum. Intense inflammation left side esophagus. F. B. not found. Neck drained externally. May 28 abscess left side esophagus; opened; F. B. not found. 6-2 ether. Almost normal. F. B. not found. May and June, 1923. Recovery.

Case 8—Mrs. A., female, 55 years. History: Painful swallowing twenty-four hours since eating beef stew. X-ray shows shadow level 6 C. V. Diagnosis: Beef bone in esophagus. Course and result: Ether, Jackson 7 mm. tube. Bone found two inches below cricoid level caught in folds of post-wall esophagus, removed. July 1, 1921. Recovery.

Case 9—M. S., male, 11 months. Six hours ago while playing on the floor suddenly choked and coughed, became cyanotic, soon normal. Repeated attacks of coughing and cyanosis, vomiting at times, blood-streaked vomitus. X-ray—No shadow; shows emphysema right lung. Diagnosis: Rabbit bone in right bronchus. Course and result: Ether, Jackson 4 mm. tube, bone found in right bronchus. Grasped and removed. Moderate laryn-

geal edema two days. Kept in hospital four days. September 4, 1920. Recovery.

Case 10—J. C., male 48 years. Last night was eating chicken, felt bone being swallowed, has dull sub-sternal pain since, worse on swallowing. Fluids and solids pass, but he is afraid to swallow. X-ray shows no shadow; after barium, shadow is outlined, 3 inches above diaphragm. Diagnosis: Flat chicken bone in lower esophagus. Course and result: Ether, Jackson 10 mm. Esophagoscope. Bone found 37 cm. from incisor teeth. Sharp projection caught in mucosa, grasped with rotation forceps, freed and removed. Normal after recovery from ether. May 29, 1923. Recovery.

Case 11—J. E., female, 45 years. History: Three days ago, while eating fish, felt sharp prick in throat, painful swallowing since, pain increased past twenty-four hours. Temperature 101, pulse 100, neck slightly swollen and tender. X-ray shows shadow in esophagus. Diagnosis: Fish bone in esophagus. Course and result: Ether, Breuning tube. Bone found in esophagus three inches below cricoid level. Mucosa markedly inflamed and swollen. Bone grasped. On withdrawal of tube and forceps, F. B. slipped from grasp. Further search failed to find it. Patient vomited on return to bed; bone found in vomitus. November 10, 1920. Recovery.

Case 12—Mrs. Q. B., female, 46 years. History: Seventy-two hours ago swallowed piece of bone while eating mutton stew. Painful swallowing since, unable to swallow even fluids forty-eight hours. Temperature 101. X-ray shows shadow level sternal notch. Diagnosis: Mutton bone in esophagus. Esophagitis. Course and result: Ether, Breuning tubes. Mucosa esophagus, red and swollen, pus in lumen. Complete esophagus searched twenty minutes before seeing foreign body. Bone found embedded in swollen mucosa; grasped and removed. Normal in two days. December 12, 1921. Recovery.

Case 13—Mrs. J. L., female, 32 years. History: Two days ago while eating chicken felt prick in throat, painful swallowing since. X-ray shows shadow after barium. Diagnosis: Chicken bone in esophagus. Course and result: Ether. Lynah esophagoscope. Foreign body found just below cricoid fold on post wall of esophagus. Little inflammation. Removed. Time, 90 seconds. December 5, 1922. Recovery.

Case 14—J. E., female, 5 years. History: Nine days

before swallowed nickel. Able to swallow liquids without pain. Four days later family doctor worked one and one-half hours under ether using forceps blindly. Since then painful swallowing. Temperature 100. Case observed four days before removal F. B. X-ray shows opaque shadow level 5th cv. Diagnosis: Nickel in esophagus. Course and result: No anesthetic, Jackson 5 mm. tube. Evidence of trauma, hypo pharynx and esophagus. Coin easily found and removed. Time 2 minutes. October 30, 1922. Recovery.

Case 15—Baby W., male, 22 months. History: Three days ago swallowed coin. Able to take liquids; gags at times. Temperature normal. X-ray shows coin in cervical esophagus. Diagnosis: Nickel in esophagus. Course and result: No anesthetic, Jackson 5 mm. tube. Coin seen and removed. Time 90 seconds. October 24, 1922. Recovery.

Case 16—H. B., female, 2 years. History: Child has been gagging three days, unable to swallow solids. X-ray, round opaque shadow in upper esophagus. Diagnosis: Nickel in esophagus. Course and result: No anesthetic, borrowed equipment, two casual assistants. After one hour's hard work managed to see coin; finally was dislodged, passing down into stomach; passed in stool next day. September 20, 1916. Recovery.

Case 17—L. S., male, 3 years. History: Two days ago swallowed penny; able to swallow only liquids. Temperature normal. X-ray shows coin. Diagnosis: Penny in esophagus. Course and result: No anesthetic, Jackson 5 mm. tube. Removed in less than two minutes. July 20, 1923. Recovery.

Case 18—W. J., male, 14 months. History: Child swallowed coin three days ago, will not swallow past twenty-four hours. Temperature 99 rectum. X-ray shows coin. Diagnosis: Penny in esophagus. Course and result: No anesthetic, Jackson child's esophageal speculum, alligator forceps. Removed in twenty seconds. March 16, 1924. Recovery.

Case 19—L. M., male, 2 years. Four weeks difficulty in swallowing, retches, able to swallow liquids easily. Temperature 100. X-ray shows shadow in cervical esophagus. Diagnosis: Metal disc from electric switch-box in esophagus. Course and result: No anesthetic, Jackson 5 mm. tube. Esophagus mucosa inflamed. F. B. found and grasped and easily removed. Time 3 minutes. July 20, 1923. Recovery.

Case 20—F. A., female, 9 years. History: Today playing in school yard, aspirated piece of metal she carried in mouth; lost voice at once, gagged and coughed. Breathing slightly obstructed. Child has the habit of swallowing metal bits, pins, nails, etc. This is first time any were aspirated. Temperature 102, respiration 24, pulse 120. X-ray shows shadow in larynx. Diagnosis: Metal curl from latheing tool steel in larynx. Course and result: Ether, Breuning laryngoscope inserted through glottis. F. B. seen below cords firmly impacted. With alligator forceps, lateral arms broken off and removed. Laryngeal edema and temperature two days. Normal in four days. November 20, 1920. Recovery.

Case 21—R. G., male, 6 months. History: Child has been gagging three hours. When this began mother missed a safety pin, put finger in baby's mouth, felt pin, unable to remove it. Fluoroscope shows pin, open, point up, to right level xyphoid. Diagnosis: Safety pin in esophagus. Course and result: No anesthetic, Jackson 4 mm. tube. Trachea and bronchi searched, no F. B. Tube passed in esophagus; pin found at lower end, point embedded in mucosa, keeper end grasped and drawn into tube. Removed. Time 30 minutes. February 24, 1922. Recovery.

Case 22—M. H., female, 6 years. History: Six hours ago aspirated safety pin, aphonia since. Diagnosis: Safety pin in larynx. Course and result: No anesthetic, Jackson child's laryngoscope. Keeper alone visible in glottis, grasped and pushed forward and down, freeing point. Removed. Time 30 seconds. April 17, 1924. Recovery.

Case 23—J. A., male, 10 months. History: Entered L. A. C. H. November 3, 1921. History of impaired respiration six weeks. Both parents positive Wasserman, child negative Wass. Culture for diphtheria negative. X-ray shows large thymus. General examination negative. Takes liquids with difficulty, breathing labored, noisy. Weight 11 pounds 11 ounces. Direct laryngoscope shows safety pin in hypo pharynx. X-ray of neck shows open pin, point up and to right. Diagnosis: Safety pin in hypo pharynx. Course and result: No anesthetic, Jackson infant's laryngoscope. Pin found in hypo pharynx, grasped with alligator forceps, point liberated. Removed. November 23, 1921. Recovery.

Case 24—A. P., female, 11 months. History: Three days ago began to cough and gag, constant cough since, fever two days. Roentgenologist examined under fluoroscope, reports pin in esophagus, level 5-7-D.V. Plate not taken. Pin found in right bronchus. Diagnosis: Beauty pin in right bronchus. Course and result: Ether, Breuning 4 mm. tube, taking fluoroscope. Esophagus explored, no F. B. Fluoroscope still shows F. B. Pin found in right bronchus, point in trachea. Point brought in tube, grasped and removed. Edema larynx, fever three days. Time 1 hour 20 minutes. July 13, 1919. Recovery.

Case 25—E. B., female, 7 years. History: January 3, 1920, developed pneumonia, told attending doctor that she swallowed large ball-bearing four days before. Eight weeks later, rib resection for empyema, no pus found. Three days later began to expectorate foul pus. Thoracotomy wound suddenly discharged pus, rapid emaciation,

clubbing fingers, chest wound closed. August 27, 1920, x-ray shows ball in left bronchus, lung abscess. Diagnosis: Steel ball-bearing in left bronchus, lung abscess. Course and result: Ether, Jackson 5 mm. tube, specially bent double cusp Breuning forceps. Much foul pus removed by suction. Granulations obstruct lumen, left lung. Ball felt in left bronchus, grasped, removed with tube, lost at glottis. Further search failed to find ball. Return to bed, ball vomited. Gained twenty pounds in forty days. Sputum free in two months. Later recurrence, still under treatment. August 31, 1920. Recovery.

Case 26—M. D., female, 2½ years. History: Two days ago swallowed carpet tack. Mother became alarmed as stools did not contain tack. X-ray showed tack in right bronchus. Temperature normal. Diagnosis: Tack in right bronchus. Course and result: No anesthetic, Jackson 5 mm. tube, side-grasping forceps. Point grasped, drawn into tube and removed tube. Time 2 minutes. July 1, 1922. Recovery.

Case 27—D. M., male, 12 years. History: May 5, 1923, aspirated screw. May 6, under ether one hour, local doctor attempted removal with bronchoscope. Brought to Los Angeles May 7. Temperature 101, respiration 30. X-ray shows large wood screw in right bronchus. Observed three days; temperature subsided. Diagnosis: Screw in right bronchus. Course and result: Butyn 5 per cent, Jackson 7 mm. tube, side-grasping forceps. Screw easily found, grasped and removed with tube. Time 4 minutes. No post-operative reaction. May 10, 1923. Recovery.

Case 28—C. M., male, 4 years. History: February 1, 1923, swallowed six-penny nail; four days later developed pneumonia; attending doctor refused to consider nail history. Fever gradually subsided, cough persisted, foul expectoration, emaciation. Moved to Arizona for T. B. X-ray June 20, 1923, showed nail in right bronchus with lung suppuration. Diagnosis: Nail in right bronchus. Course and result: Butyn 5 per cent, Jackson 5 mm. tube, side-grasping forceps. Nail found, extending into trachea from right bronchus, foul pus. Nail grasped and removed. X-ray of chest four months later shows no pathology of lungs. May 1, 1923. Recovery.

Case 29—H., male, 49 years. History: Three days ago dentist gave gas to extract crowned third molar. Tooth broke off and was lost down throat. X-ray showed crown in right bronchus. Patient has had pulmonary T. B. Diagnosis: Gold crown in right bronchus. Course and result: On August 18, 1922, Bronings' instruments, Dr. B. worked one hour, cocain anesthetic, sitting position, unable to grasp tooth. August 19, 1922, Jackson 9 mm. tube, Boyce position, tooth removed in 4 minutes, rotation forceps. August 19, 1922. Recovery.

Case 30—R. S., male, 15 months. History: Six weeks ago was playing with walnut shells; gagged and vomited. Mother gave castor oil. Fragments of nutshell in stool. Breathing noisy. Takes fluids, fever one week. Local doctor advised adenoidectomy. Temperature 100, pulse 120, respiration 24. Chest examination negative. X-ray shows no F. B. Diagnosis: Piece walnut shell in hypo pharynx. Course and result: Chloroform, Jackson infants' laryngoscope. Intense inflammation, granulations, swollen tissue. Shell found in hypo pharynx, grasped with alligator forceps, rotated and slowly removed. Child normal in few days. March 2, 1920. Recovery.

Case 31—R. M., male, 2 years. History: One and one-half hours ago, eating walnuts, choked and coughed; aphonia and labored breathing since. X-ray negative. Diagnosis: Walnut shell in larynx. Course and result: No anesthetic. Jackson child's laryngoscope. Shell found wedged in glottis, grasped with alligator forceps, rotated and slowly removed. Kept under observation twenty-four hours. Time 40 seconds. January 30, 1924. Recovery.

Case 32—K. P., female, 3½ years. History: May 13, 1923, eating sunflower seeds, choked, cyanos at times, cough. Entered L. A. G. H. May 14. Labored breathing. Temperature 101. "Tracheal thud" present. X-ray negative. Diagnosis: Sunflower seed in trachea. Course and result: No anesthetic, casual assistants. Unable to introduce tube (poor exposure larynx); laryngeal edema increased. Tracheotomy. Seed coughed through tracheal wound. Broncho pneumonia developed May 14, 1923.

Case 33—H. J., male, 17 months. History: Three hours ago choked and became cyanotic while playing with beans. Hypertympany over right chest; absent breath sounds over right chest. Diagnosis: Bean in right bronchus. Course and result: No anesthetic. Jackson 4 mm. tube, Breuning double-hook forceps. Bean found in right bronchus, grasped and removed with tube. Time 3 minutes. Was allowed to go home. Twelve hours later laryngeal edema. Tracheotomy not permitted by parents. Atropin given; better. Sudden cyanosis and death fourteen hours after operation. April 8, 1922. Died.

Case 34—E. L., female, 18 months. History: Six days ago playing on the floor, choked and became cyanotic; four days later, cough, temperature 102, rapid respirations. Continued fever since. At L. A. G. H., F. B. diagnosed. X-ray shows air trapped, right lung. Diagnosis: Almond kernel in right bronchus. Course and result: Butyn 5 per cent, Jackson 4 mm. tube. Mucosa right bronchus, swollen; nut fragment found and removed. Laryngeal edema increased; tracheotomy required in forty-eight hours. Tracheal tube removed in one week. December 21, 1923. Recovery.

Case 35—I. J., female, 16 months. History: Four days ago while eating peanut candy, choked and coughed. Forty-eight hours later temperature 102, pulse 120, at

L. A. G. H. Air trapped right lung, demonstrated with x-ray. Diagnosis: Peanut in right bronchus. Course and result: Butyn 5 per cent, Jackson 4 mm. tube. Fragment of nut kernel found in right bronchus; mucosa swollen; removed. Time 4 minutes. Normal in four days. September 12, 1922. Recovery.

Case 36—F. W. F., male, 45 years. History: Five days ago while eating plum pudding, had sudden, complete obstruction to swallowing. At 18 years of age had esophageal obstruction due to lye; treated by dilation. X-ray shows filling defect at diaphragm. Diagnosis: Plum pit in esophagus. Course and result: Ether, Breuning's tube. Esophagus narrowed, old scars. F. B. found, grasped and removed to cricoid, where it slipped from forceps. Further search unsuccessful. Able to swallow for twenty-four hours, when complete obstruction again occurred. F. B. again found and removed. August 8, 1920. Recovery.

Case 37—C. S., male, 12 years. History: Three days ago swallowed marble; complete obstruction to swallowing since; no pain or other symptoms. X-ray shows shadow level 6 d. v. Diagnosis: Marble in esophagus. Course and result: Butyn 5 per cent, Jackson 7 mm. tube, spoon. Unable to grasp F. B. It was pushed into stomach; passed in stool next day. November 20, 1922. Recovery.

Case 38—M. M., female, 2 years. History: This morning child swallowed a large cuff button; choked, became cyanotic. X-ray taken two hours later shows cuff button in thorax. Diagnosed by roentgenologist as in trachea. Child has frequent colds and tonsillitis; two days has had a cold. Diagnosis: Cuff button in esophagus. Course and result: Butyn anesthetic, diagnosis accepted from x-ray report—plates not seen by operator. Bronchoscopic search; no foreign body; trachea inflamed; edema larynx. F. B. found in esophagus; pushed into stomach; passed in stool ten hours later. Laryngeal edema increased. Tracheotomy necessary. December 16, 1923. Recovery.

Case 39—J. W., male, 20 months. History: Difficulty in swallowing thirty-six hours. X-ray shows no F. B. Temperature normal. Diagnosis: Coat button in esophagus. Course and result: Butyn 5 per cent. F. B. seen tightly wedged in esophagus three inches below cricoid. Ether given. F. B. loosened and removed. June 13, 1923. Recovery.

Case 40—A. A., female, 5 years. History: While being treated with intubation for laryngeal stenosis, aspirated O'Dwyer tube. X-ray shows tube in left bronchus. Diagnosis: O'Dwyer intubation in left bronchus. Course and result: Butyn 5 per cent, Jackson 5 mm. tube. Expanding forceps inserted in lumen of tube. Removed F. B. August 16, 1922. Recovery.

DISCUSSION

Chester H. Bowers, M. D. (1136 West Sixth Street, Los Angeles)—Dr. Jesberg is extremely fortunate in being able to present so many cases of foreign bodies in the respiratory and digestive tracts with such favorable outcome. It is highly desirable that such papers be brought to the attention of the general profession, as even today there is current among some of our number the belief that a foreign body is a very rare thing and that if it occurs there is nothing to be done.

Two years ago I removed a rivet after seven months' sojourn from the posterior division of the right inferior lobe bronchus. Although the boy gave the history of aspiration of the foreign body, the parents were informed that the rivet would not go down into the lung, and if it should it would be safer to let it remain than to encounter the danger of removal. Removing the rivet caused no reaction, but cured the child from a lung abscess which had formed.

Another point that the essayist made is to guard against hasty removal of foreign bodies.

The removal of foreign bodies is seldom an emergency operation, and I feel that it is a serious mistake to operate until the case has been properly studied, the exact location of the foreign body determined, the team assembled and the patient properly prepared. Personally I prefer doing these operations early in the morning in contradistinction to rushing about all day in an effort to wildly extract the foreign body at the soonest moment. These are factors which are apparent to every bronchoscopist, but are not generally appreciated by the medical profession.

George W. McCoy, M. D. (Security Building, Los Angeles)—This line of work is a specialty within itself, handicapped by not sufficient revenue to afford a living for the operator and his team workers. About all the financial returns in the majority of cases is the coin removed, and sometimes the patient is offended to give that up. With few exceptions the operator has

to make his living by other work and to make this line practically charity work. The laity nor the medical profession in general do not appreciate the great amount of time and practice necessary to do good work. Without the careful procedure so thoroughly worked out by Jackson, without the requisite skill by the operator and his team workers, the attempt at removal of a foreign body should not be made.

Dr. Jesberg is to be honored that he devotes so much of his time to this work and does it so skillfully.

I would like to report two interesting cases.

A child about 3 years of age had a few pennies in his mouth. X-ray showed one distinct shadow and a faint one somewhat overlapping in the esophagus as if the patient might have moved or there were two pennies. I did not know which. Two pennies with one grasp of the forceps were removed, without anesthetic and without the slightest damage.

A boy about 13 years of age, while running with a silver-plated collar button in his mouth, choked somewhat when the collar button went down. X-rays were taken and reported negative. For about fourteen years the young man coughed and expectorated a muco-purulent sputum and then he reported to Dr. Soiland, who made the proper diagnosis by x-ray and sent the patient to me. At the end of the lowest branch of the right bronchus was an almost closed abscess about two and a half inches in diameter with a small opening surrounded by a firm fibrous ring so small that Jackson's forceps would just pass through. Three separate attempts were made at about one month intervals with local anesthetic to the pharynx and larynx. By the use of Jackson's bronchoscope and the fluroscope to direct the forceps the button was removed without any mishap. In a short time the muco-purulent expectoration and cough disappeared. X-ray showed the abscess gone. The patient resumed his collegiate studies. Dr. Detling, who worked with me on this case, and I were greatly pleased. The collar button had about half disappeared by chemical reaction.

Harvard McNaught, M. D. (Butler Building, San Francisco)—I have enjoyed Dr. Jesberg's excellent and timely paper, and wish to congratulate him on the results of his careful work.

We have all had these problems to meet in this work, and one must be more resourceful in this procedure than in any other branch of surgery, as entirely new situations are continually presenting themselves. Preparedness is a sine qua non of this work, and haste is very seldom called for. The thing that is brought most forcibly to my mind at this time is that some one man or group of men should be given these cases in each vicinity. No one man has enough of such patients to acquire the necessary dexterity.

Where there is a teaching institution they should have a complete equipment for such work, and it would be logical to refer cases there. It is subjecting the patients to unnecessary risks to hold such cases oneself, unless one is constantly in practice. If all cases were so referred in a neighborhood to one man or a group of men the number would be sufficient to keep them in training to do the best for the patient by acquiring the necessary dexterity in handling such cases.

Problem of Health Education—Health education in our schools is receiving a lot of attention on the part of educators, and we are not disposed to condemn the idea, but we are opposed to the kind of health education that is being given out by a lot of school teachers who are proselytizing for the Christian Scientists, chiropractors, and other medical pretenders. All health education in our schools ought to be under the supervision of health officers who are reputable medical men, and not given by teachers who have fantastic and inconsistent ideas concerning health and its preservation.—Indiana Medical Journal.

THE TREATMENT OF FLEXION DEFORMITY OF THE HIP JOINT

By S. F. STEWART, M. D., Los Angeles

In a partially paralyzed individual suffering from a flexion contraction of the thigh, an attempt should be made to preserve as much muscle-power as possible for future use.

Where the tensor fascia remains active, it should not be divided transversely as in the operation of Soutter, but should be lengthened in its tendinous portion, and the transplantation of the lesser gluteals after the manner of Campbell should be held as a reserve measure.

DISCUSSION by Harold H. Hitchcock, Oakland; H. W. Spiers, Los Angeles; A. Gottlieb, Los Angeles; Ethan H. Smith, San Francisco.

FLEXION deformity at the hip may be due to disease of the bones or joints, or a contracture of the soft parts. It may be simple or associated with abduction or adduction. The deformity due to bony lesions will not be considered in this paper. The contracture of the soft parts results chiefly from improper prophylaxis in poliomyelitis, spastic paraplegias, arthritis, and the retention of an amputation stump in a faulty position for an unwarranted period.

If the distortion is unilateral and very marked, the unfortunate usually prefers to use a crutch, making no attempt to place his foot on the ground. A slight or moderate bilateral contracture is compatible with biped progression if the paralysis of the remaining musculature is not too severe. Campbell states that, if the bilateral contracture is greater than 60 degrees, the individual is compelled to assume the quadruped form of locomotion. In some unilateral cases, where the person has permitted the affected member to dangle, it has been observed that there is marked shortening of the bones of both the upper and lower leg. After the deformity has been corrected and the person begins to use the leg, a compensatory growth apparently begins.

Soutter, in 1914, described an operation which, in its essential features, consisted in the exposure of the deep fascia of the thigh at the level of the anterior spine, a transverse division of the tensor fascia from the anterior superior spine to the trochanter, a sub-periosteal stripping of the inner and outer aspect of the ilium and the removal of the anterior superior spine. This operation gave a great deal of satisfaction. Campbell, in 1923, described a more radical procedure, wherein the gluteal attachments to the iliac crest were transferred to a point about an inch above the acetabulum, and the structures attached to the anterior superior spine were permitted to attach at a more inferior position.

These operations work very well in selected cases, but there is a group of cases to which neither procedure is applicable. It would, therefore, seem wise to evaluate the groups to which each operation is applicable. In the operation described by Soutter, there is frequently a division of manifestly good muscle in the belly of the tensor fascia femoris at the time that the overlying fascia is divided transversely. It is a well-recognized fact that the transverse division of the belly of a muscle weakens the muscle in proportion to the amount of muscle separated from its nerve supply. Hence, it would appear inadvisable to perform the Soutter operation

on any individual who showed any power in the tensor fascia femoris and in whom it might be advisable at a later time to transplant the tensor fascia to take the place of the quadriceps femoris or the gluteus medius.

It is likewise patent that when an elastic structure, such as a muscle, is on tension between two points of attachment, that the shortening of the distance between these two points reduces the tension exerted and likewise reduces the range of contractibility, and thereby amounts to a partial paralysis of the muscle. This, in short, is what is accomplished by the operation as described by Campbell, in case there is any power left in the glutei which he transplants.

If, therefore, an operative procedure can be devised which will avoid destruction of the tensor fascia even in a slight degree, and which will retain whatever power remains in the lesser gluteals, and yet permit of the correction of the flexed or the flexed and abducted position of the thigh, it would seem wise to use such a procedure in all cases where power in the tensor fascia and the gluteals can be demonstrated.

Therefore, it would seem proper to review briefly the physiological anatomy of the affected region, and endeavor to indicate the methods of differentiating the various groups. The tensor fascia femoris is the lateral stabilizer of the pelvis when the thigh is flexed, as in walking upstairs; the lesser gluteals, on the other hand, are the lateral stabilizers when the thigh is extended, as in ordinary walking. By the same token they may be demonstrated on examination, respectively, as the abductor of the hip in flexion, and the abductors of the hip in extension. If, therefore, the patient can abduct the thigh while it is in a flexed position, it would seem reasonable to believe that the tensor fascia was present to a greater or less degree, and an attempt should be made to avoid the partial destruction of that muscle by the transverse division of some of its fibers at the level of the anterior superior spine. With a hip drawn up in flexion, it is impossible to evaluate the lesser gluteal muscles, and hence it would seem unwise to weaken them unnecessarily by such an operation as that of Campbell, who believes that where the abduction contracture is great that the operation which he has described is the one of choice. On the other hand, it is our belief that, in orthopedic surgery, one should be governed by the following principle, that when in doubt, always do the least radical thing, knowing that if it does not yield the desired results, the more radical procedure can be undertaken at any time. To avoid these objections, the following operation has been devised. A longitudinal incision is made from the iliac crest to a point one inch below the level of the perineum, and about one and a half inches posterior to the anterior superior spine. The deep fascia is exposed and freed from the overlying tissues till the anterior and posterior borders of the tensor fascia femoris are exposed. The muscle is then isolated from the anterior superior spine to the level of the perineum where the fleshy belly of the muscle terminates. The fascia is divided by a "Z" incision, as is done in lengthening the tendo-Achilles, and the fascia is sutured in the

Figure 1—Showing the point of lengthening of tensor fascia femoris, together with the loosening of muscle from the anterior superior spine.

lengthened position. The periosteum over the anterior superior spine is incised and the periosteum is stripped on the inner and outer sides of the pelvis, as in the manner of Soutter. The leg is drawn back into an extended position, and any tight fibers that remain are cut transversely. The wound is then closed, a simple dressing applied, and the patient is returned to the ward.

Although no difficulty has been experienced in the after care of patients treated by this operation, the unfortunate results that have attended immediate hyperextension in plaster jackets in the hands of other surgeons has led to the adoption of the following technique in the after care. Ten days later, when the stitches are removed, a snugly fitting plaster jacket, or jacket spica of the unoperated leg, is applied with the back in the flattened position, and the operated leg is enclosed in a long plaster boot. The patient is then placed on a frame that was described in a previous communication, and the limb gradually hyperextended. The abduction or adduction element is taken care of by lateral traction on the plaster boot. After being hyperextended for a period of six weeks, the plaster is removed and any further operative procedures are undertaken. In the event that one is now unable to correct the abduction element in the deformity, one can then with a clear conscience undertake the operation of Campbell, although in the half-dozen or more cases in which this operation has been done no occasion has been found that required further operative correction. If, after the patient is gotten up and has had his muscle-training it is found that there is a gluteus medius limp, an unimpaired tensor fascia can be transferred to the trochanter after the manner of Legg.

SUMMARY

In a partially paralyzed individual suffering from a flexion contraction of the thigh, an attempt should be made to preserve as much muscle power as possible for future use. To this end, in cases where the tensor fascia remains active, it should not be divided transversely as in the operation of Soutter, but should be lengthened in its tendinous portion, and the transplantation of the lesser gluteals after

the manner of Campbell should be held as a reserve measure.

902 Union Bank Building.

DISCUSSION

Harold H. Hitchcock, M. D. (Medical Building, Oakland)—The tensor fascia latae muscle is supplied by a branch of the superior gluteal nerve which passes through the gluteus medius muscle to the upper third of the tensor fascia latae, and then extends distally from this point, supplying the deep surface of the muscle with small rami.

It is thus obvious, as pointed out by Doctor Stewart, that it is a needless waste of muscle tissue to cut this muscle through its belly. In all cases where one is apt to need the tensor fascia latae for transplant later, I think Stewart has taught us economy. However, in cases of flexion resulting from spastic paraplegia, I would prefer the procedure of Soutter.

For his frame and for this lesson in muscle economy, to aid the correction of these hip flexion cases, Stewart is to be congratulated.

Too much emphasis cannot be placed on the dangers of trying to hyperextend hip flexion cases immediately after operation, especially by the application of plaster of paris spicas.

H. W. Spiers, M. D. (Westlake Professional Building, Los Angeles)—Doctor Stewart has pointed out a refinement of value in cases where the Soutter operation has been previously routinely used. The tensor fascia femoris muscle can frequently be made of use to the individual with paralysis in the gluteal region. It is quite frequently the only muscle not to some extent affected by the paralysis. I have seen several of the doctor's cases in which he has preserved this muscle and later used it. These showed the distinct advantage of the method.

Regarding the immediate post-operative use of fixed hyperextension, I would like to add my word of caution. Until I adopted the plan of not putting on such casts, I rather dreaded the post-operative reaction of my patients. I avoided using this operation, on this basis, in patients that presented an unusual operative risk. There were no fatalities, but I had several in a series which gave me very considerable concern. I am now using, routinely, the method as described, and my experience in this regard has been very satisfactory.

A. Gottlieb, M. D. (607 South Hill Street, Los Angeles)—It has been my good fortune to assist the author in three of his operations for the lengthening of the tensor femoris fascia, and to follow the cases post-operatively. The operation impresses one with its simplicity and its sound physiological judgment that the greatest contracture is present in the fascia and not in the muscle substance, the resistance of which can be overcome by subsequent physiotherapy. It is the fascia which needs elongation, and not the muscle which is being cut across by the method of Soutter to gain the necessary correction of the hip. The favorable

results seen in the above three cases leads me to believe that the Stewart operation is indicated in most all hip flexions due to contracted soft tissues. An exception to this may only be such cases where the operator deliberately desires to destroy nerves supplying the muscle substance, as in marked spasticity where the Soutter may be preferable or where there is, in addition to flexion, a very resistant abduction of the hip, for which a Campbell procedure may find indication. The Stewart operation, with its outlined after treatment, is indeed a valuable contribution to orthopedic surgery.

Ethan H. Smith, M. D. (Flood Building, San Francisco)—The operations mentioned by Doctor Stewart for flexion deformities of the hip-joint such as Soutter's and Campbell's, and a modification by Doctor Stewart himself, have a very limited range of usefulness, in my opinion, if indicated at all.

From a study of the action of the hip-joint, it would seem that the muscles involved in the above-mentioned operations are in but a small measure to blame for the deformity. The muscles most involved are the psoas and iliacus with the combined tendon attached to the lesser trochanter, which is the direct flexor of the thigh. Almost invariably the adductor group is also greatly contracted in these cases. The tendons of the psoas and iliacus muscles are well-nigh inaccessible for extensive operation. Tenotomy of the adductors is a very simple and a very useful procedure in many cases where they are contracted.

The cutting transversely of the body of a muscle, and especially the muscles involved in the operations under discussion, is never warranted by any compensatory improvement in function. The transverse cutting of a muscle is well-nigh uncalled for in any surgical procedure. The psoas and iliacus muscles can nearly always be lengthened by traction. They are not prone to contracture.

To use a popular way of expression, the best method of cure is the prevention of deformity in the beginning of the trouble. This is quite possible if the cases are placed in the hands of surgeons trained in orthopedic work right at the beginning. I would ask that every influence be brought to bear on the medical profession as a whole, to pay more heed to turning these cases of deformity, and many others, over to the orthopedic surgeons just as soon as a diagnosis is made. Telling parents that "the child will outgrow the trouble," or wasting valuable time in useless and unskillful endeavor, brings the case to the orthopedic surgeon in a condition when perfect cure is impossible.

Doctor Stewart (closing)—I would like to take issue with Doctor Smith in two matters, first in regard to the responsibility of the psoas and iliacus in causing flexion deformity. I have never seen a case of contracture at the hip where these muscles were responsible, and I believe my memory is correct when I say that the late Doctor Robert W. Lovett told me he had never seen a case of flexion contracture in which operative measures were necessary on the ilio psoas group. When such a careful observer, and one who had such a large experience in the treatment of these conditions could say that, I doubt very much whether many cases are due to this group of muscles.

As to the responsibility of the adductors, I can only say that adductor contraction is rarely present in infantile paralysis, but is frequently responsible for a portion of the deformity in spastic paralysis and in arthritic conditions.

In the next place, I feel that Dr. Smith is rather radically conservative in advising traction for the removal of the severe deformities of the hip in infantile paralysis. If he were confining his remarks to arthritic conditions of the hip, I would heartily agree with him in the use of traction. In the paralytic contracture, however, I must disagree with him. For many years Soutter endeavored to treat these conditions by non-operative procedures, only to meet with disappointment, and it was these unfortunate experiences that finally compelled him to devise and practice the operation which bears his name. My endeavor has been limited to an attempt to add a refinement of conservatism to the pioneer work of Soutter.

I thoroughly agree with the plea for preventive orthopedics, especially in infantile paralysis.

RATIONAL CONDUCT OF LABOR

By HARRY S. FIST, M. D., Los Angeles

Physician must know what should be done and what left undone.

A plea for physiologic midwifery.

Much of present surgery in obstetrics unwarranted.

The physician's services should date from early pregnancy to complete involution of the uterus.

The lazy doctor should not do obstetrics.

DISCUSSION by E. J. Krahulik, Los Angeles; John Uruwink, Los Angeles; Elizabeth Keys, San Francisco; G. Carl H. McPheeters, Fresno.

THE modern physician has a regrettable tendency toward the use of complicated and involved methods for the accomplishment of plain and simple tasks. The obstetrician is no exception.

The older generation of obstetricians would tie the umbilical cord with a piece of sterile tape, and the result was satisfactory. The newer generation must needs have some sort of a special clamp or technique for performance of the same task. All manner of bizarre maneuvers are advocated and used to deliver the child, when a simple procedure assisting the mechanism of labor would effect delivery. It is a glaring fact that, in spite of all our efforts, the relative mortality rate for parturient women, as the result of sepsis, has not materially diminished in the last twenty-five years.

Something seems to be wrong with our work. Obstetric patients require care from the time of conception to the end of involution. Why do they not obtain it? Delivering the baby is by no means the whole story. The ultimate aim is to have a well mother and a well baby.

PRENATAL

A careful history and a complete examination, instructions as to diet, care of breasts, exercise, clothing, and coitus, are essential in every case. Examinations of urine and of blood pressure at frequent intervals are of the utmost importance.

Previous to the onset of labor, the pelvis and its contents should be studied carefully and the findings recorded. The shape and size of the pelvis should be known, and a pre-labor study made of the position, presentation, and size of the fetus, especially the head.

George Ernest Herman goes so far as to state in his book, "Difficult Labor," "Almost all difficult labors are the result of faulty diagnosis, not only of the position of the fetus, but also of disproportion between the size of the fetus and the size of the pelvis."

LABOR

If labor is to be attended efficiently, it is necessary to know the anatomy of the birth canal and to understand the share each structure has in the mechanism of labor. With this knowledge, the forces nature intended will be applied, instead of the present-day spectacular makeshifts. No matter how careful our aseptic precautions, we endanger the patient's life every time we invade the birth canal. Statistics show that 40 per cent of all fatal septic cases have had some sort of operative interference. How much better it would be if we could more often terminate labor without the performance of

version or the application of fearfully and wonderfully designed forceps, for mother and baby would then both be in less danger. The dangers of a breech presentation may often be avoided by external version prior to the onset of labor. Induction of labor, because of a borderline pelvis, may render a Caesarian section unnecessary.

FIRST STAGE

The uterine contractions are in the upper uterine segment. The lower uterine segment dilates as the upper contracts and retracts, pulling the lower against the presenting part, aided by the hydrostatic pressure of the bag of waters. The child cannot be expelled until the cervix is fully dilated. Clearly, then, the patient should not bear down during the first stage of labor, for the presenting part, surrounded by the lower segment, would be wedged into the pelvis, and dilatation thus retarded. The patient would tire herself out without making any progress. The supports of the uterus would be pulled down, laying the foundation for "falling of the womb," at a later date.

It is possible to know the condition of the cervix, and the progress of the presenting part, by means of rectal examinations at intervals. Until the cervix is fully dilated the patient should not bear down, and should rest between pains. She should have light, easily assimilable food at regular times, and sedatives if indicated.

SECOND STAGE

The second stage of labor is one of active work. The responsibility for this stage rests entirely with the doctor. The man who goes to bed and has the nurse call him when the head is being born is in a class with the midwife; for, if he has the knowledge, he is not at hand to apply it. Worse than the lazy man is the one who unnecessarily invades the birth canal, for he increases the danger of infection, and the patient would be much better off without him.

The bag of waters protects the child and helps dilate the cervix. When the cervix is fully dilated, if the membranes are not already ruptured, this should now be done, or progress is impeded.

In this stage the patient should assist every pain with voluntary efforts, and should receive instructions from the doctor so that she may know how best to do so. If she does not assist, contractions often become weak or die away entirely. If she is reassured and urged to further efforts, to simulate straining at stool, to work throughout the entire course of every pain, and to rest between pains, labor will proceed much better. When pains are tumultuous and labor too precipitate, the patient should refrain from bearing down, or be given a sufficient amount of anesthetic to retard the pains.

In order for delivery to take place, the fetal presenting part must flex, descend into the pelvic cavity, and flex further at the pelvic floor, when rotation and delivery follow.

If flexion does not take place, labor stops. This is, in most cases, due to the inability of the uterine and abdominal muscles to exert enough pressure. Therefore, some method for assisting these muscles to produce flexion of the presenting part seems the logical procedure. The tight abdominal binder, as

used by Beck of Brooklyn, does the work very well. In its simplest form, this binder is a piece of strong cloth, pinned tightly around the abdomen with safety pins. It may be made as a front and a back piece, with buckles and straps on each side. With this support, the patient can exert more pressure, so that flexion takes place and labor proceeds, saving the mother and baby hours of stress and danger. In cases of pendulous abdomen, the effect of the binder is often magical.

"Puller-straps," are helpful. They should be short enough so the patient need not bend the elbows, but can pull straight from the shoulders.

During the second stage, the fetal heart should be carefully checked after every pain by means of the head stethoscope. If slower than 100 per minute, faster than 160 per minute, irregular, or failing to return quickly to normal after each pain, it is a sign of too much compression of the child. The appearance of meconium with a vertex presentation also indicates danger. Upon the development of any of these signs, the binder should be removed and the patient asked to cease all voluntary efforts until the heart is normal, after which more caution is used as to the pressure applied.

A lacerated or relaxed perineum does not flex the head well so that rotation will follow, and has lost the funnel-shape which is so important in directing the occiput forward. It is, therefore, very often a great factor in delayed rotation. Steps should be taken to restore such a perineum to as nearly its normal function as possible. To accomplish this, the thighs should be flexed tightly on the abdomen during each pain, when the head is on the perineum. This tightens the perineum much as the same process would tighten the seat of a man's trousers. As a result, the head flexes, rotation takes place, and many a so-called persistent occiput posterior is avoided. Why, then, attempt forceps extraction or methods of rotation which involve invasion of the uterus, before trying this simple procedure? The mother and baby are entitled to all the safety we can give them.

When the head begins to come through the vulva, the patient should be given sufficient anesthesia to cause partial subsidence of pains; the thighs should be extended to relax the perineum, and a hand placed over the head, slowing its progress and directing it forward against the pubes.

As soon as the head is delivered, search should be made for coils of the cord about the neck. These may be brought up over the head, or slipped down over the shoulder. If neither can be done, two clamps may be applied and the cord cut between them.

The head should be depressed, so the anterior shoulder will slip out under the pubic bone. The head should then be elevated, and the posterior shoulder will pass out over the pelvic floor. Since the bulk is decreased by the anterior shoulder being out of the way, there is less chance of causing a laceration. The rest of the body easily follows.

Mention of the fact that the bowels and bladder should be empty, and that strict aseptic and antiseptic precautions should be observed, seems unnecessary; but the sad fact remains that many obstetricians disregard these important things. The feasibility of forceps extraction, version, or Caesa-

rian section, is always considered; but the necessary practical procedures which are at our command are dismissed without a thought.

THIRD STAGE

From the time the baby is born until the placenta is expelled, the assistant or nurse should keep one hand on the fundus and gently rub its surface if there is relaxation. There is no especial hurry about delivery of the placenta, so the baby may first be taken care of. It should be made to breathe properly, first milking out the trachea with the finger on the front of the neck, and then stimulating respiration by running the hand quickly up and down the spine. The baby should never be struck over the kidneys. It is well at this time for the doctor to cleanse the face and place the prophylactic in the eyes. The cord may be tied when it stops pulsating, and a sterile alcohol dressing and binder applied.

If, at the end of twenty minutes, signs of separation of the placenta are evident, the thumb may be placed in front of the uterus, the four fingers behind, and the two brought gently together to assist expulsion. Manual removal of the placenta should be regarded as a major operation. The cord should never be used for traction. The placenta should always be examined to see that it is complete.

At the end of the third stage, the cervix is usually low in the pelvis. The large veins brought with it are kinked and stretched, so the tendency is toward congestion and hemorrhage of the uterus. By means of one or both hands, applied above the pubes, the uterus can be brought up into the abdomen, lessening the danger of hemorrhage and increasing the chances of ultimate proper position of the uterus. At this time the patient may be given ergot or pituitrin, and the uterus should be watched for at least another hour.

Examination of the cervix and perineum may be made at once or after an interval of seven days, but, in every case, all lacerations should be repaired.

PUERPERIUM

The duties of the obstetrician are not ended when the uterus is emptied. The patient should be seen daily during the lying-in period. Careful attention must be paid to the diet, the breasts, the temperature, the bowels, the lochia, the uterus, and many other details. Properly directed exercise will do a great deal toward hastening good involution. The baby must have the same sort of care as to abnormalities, umbilicus, prepuce, tongue, bowels, weight, eyes, and numerous other things.

Every conscientious obstetrician will insist on making a thorough examination of mother and baby about a month after the delivery so that he may administer whatever treatment is necessary. If this is done, there is no excuse for leaving uncorrected a malposition of the uterus, or neglecting a badly bulging umbilicus.

SUMMARY

Prenatal care, including complete examination for every patient.

Proper preparation for labor.

Rest during first stage; hard work, and protect maternal structures during second; ample time during third.

When cervix fully dilated: rupture membranes; tight abdominal binder; properly adjusted pullers; flexion of thighs. Close check on condition of baby.

Replacement of uterus after expulsion of placenta.

Post-partum care, to include examination one month after delivery.

Westlake Professional Building.

DISCUSSION

E. J. Krahulik, M. D. (6422 Hollywood Boulevard, Los Angeles)—Dr. Fist's plea for physiological obstetrics, at a time when operative delivery is the fashion, should be commended. At present little attention is directed toward the first stage. Sad experience has taught us that attempts at delivery before the cervix is fully dilated are mutilating and often disastrous. The various interferences have, therefore, been postponed to the second stage.

One needs to remain with but a few women during their labor, and he will realize that the second stage is relatively comfortable. When the cervix is fully dilated, one can safely predict a termination within two hours. Three or four drops of chloroform properly administered with each pain will make the patient comfortable. I am familiar with a labor routine similar to the one described which is used by Polak at the Long Island College Hospital, Brooklyn. Forceps are rarely necessary, second stages usually terminate within two hours, and there is little anxiety about posterior positions. The head does not rotate until it reaches the levators, consequently there is little cause for alarm before the cervix is dilated. If at this time there is someone present to direct the patient's efforts, such misfortunes as deep transverse arrest and unrotated posteriors will be historical.

Does the obstetrician who performs a version or applies forceps unnecessarily blame himself for his invalids, as well as his deaths? Does the hour of labor that the patient has avoided sufficiently compensate for the possibility of years of discomfort from a chronic parametrial inflammation, and later for an operation when some hopeful gynecologist will sacrifice a cervix and perhaps a normal tube and ovary trying to cure this pain? When these conditions do occur and one has not done any operative procedures, "the peace of mind surpasseth all understanding."

Our conservative efforts should be directed to the first stage. It is most unmercifully neglected. Usually the patient is allowed to suffer alone in a room. Occasionally a nurse or the doctor stops long enough to tell the patient that "she must help herself," and instructs her to "bear down." How grateful a patient is when someone remains with her to comfort and encourage her. A noisy patient becomes calm and will rest between pains. Knitting or reading magazines are hardly outbursts of sympathy.

Analgesia during the first stage is still a glaring field for investigators. An analgesic must be fool-proof and must not carry any possibilities of complications. Where it is not contra-indicated because of the patient's general condition, gas will alleviate the suffering. It is practically harmless, but rather expensive. Morphine scopolamine may be used safely by trained obstetricians when there is an ample pelvis, but increases the incidence of forceps. The man who promiscuously promises a painless labor is dangerous.

Contracted pelvis with a diagonal conjugate of 10 cm. or above should be given a test of labor; that is, a second stage of at least four hours managed as outlined by Dr. Fist. Should the head fail to engage, a two-flap low-incision Caesarian section could then be performed. In a series of cases where this plan was followed, borderline and flat pelvis occurred about fifty-five times per thousand, but the incidence of Caesarians was only 0.8 per cent. Inducing borderline pelvis would require many unnecessary inductions; some cases might not be induced in time, others would give very small babies.

John Vruwink, M. D. (Pacific Mutual Building, Los Angeles)—Two years in a mining camp in Arizona afforded me an opportunity to watch the immediate results in about five hundred labors. The patients were, for the most part, Mexicans. There was practically no prenatal care, the management of labor consisted, in general, in conducting the second stage. The outstanding fact in my mind was the high proportion of spontaneous labors, the

total absence of eclampsia, the absolute rarity of sepsis, and post-partum hemorrhage.

This was an interesting comparison to a series of cases followed at the Chicago Lying-in Hospital, where the conduct of labor was one of activity in the second stage, namely, prophylactic forceps.

The habitat and life of the woman in the open and her increased capacity for work and pain were no small factors, in the matter of comparison, to the artificialities surrounding the life of the patient in a large city.

The Los Angeles Maternity Service is now conducting more than 100 labors per month. Since its inception the slogan has been "Intelligent Watchful Expectancy." A maternal mortality of one death to 734 deliveries and an infant mortality of less than 5 per cent, including all stillbirths and deaths within ten days, is more than presumptive evidence that we should continue this course.

The end-result, as Dr. Fist emphatically states, is a well mother and a live and normal baby. Such a result is obtainable not merely by conservative management, but conservative management intelligently applied. We will always face the possibilities of hemorrhage, there is disproportion between passenger and passage, not always discernible before labor, and there is sepsis even in spontaneous labor, with no examination or interference. Occasionally, an eclampsia occurs, in spite of judicious management, because of our imperfect knowledge of its etiology.

I do not believe that the midwifery practiced in Arizona equals in results, particularly for the mothers, the end-results obtained in later observations. Neither do I believe that forceps—or version and extraction—may be indiscriminately applied, and that results can approximate the end-result of normal spontaneous labor, intelligently directed according to the principles of this paper. No one, however, who sees much consultation practice can hide the fact that conservative obstetrics ceases to be intelligent conservatism when factors are present or arise during the management of labor causing dystocia. A plea for conservative obstetrics is equally a plea for intelligent interference.

Dr. Fist is to be decidedly encouraged in his plea for rationalism, more attention to prenatal care; more thoughtfulness for the first stage of labor; more intelligent management of the second and third stages of labor; and watchfulness during the puerperium, both for mother and baby.

Elizabeth Keys, M. D. (391 Sutter Street, San Francisco)—Discussion of obstetrical subjects has so tended to the spectacular that the physiological phases of pregnancy and delivery must risk lack of savor. It seems a pity that with so many fundamental problems still untouched, time, labor, and interest should be spent on more or less dramatic detail.

Prenatal care means that at all stages of pregnancy the doctor has a clear picture in his mind of the mother, her baby and their reaction to each other. While safe-guarding the patient, this also greatly relieves the physician of the sickening terror of the unexpected, an experience that may visit the most careful in a fulminating toxemia or sudden violent hemorrhage.

Prenatal care means also attention to all the small details of the patient's life, common sense hygiene, explanation of discomforts, reassurance oft repeated, neighborly experience and advice modified or utilized, morale sustained—and *only on indication* does it mean radical departure from the patient's ordinary mode of life.

It is unnecessary to discuss further Dr. Fist's presentation of the mechanics of labor, but we cannot resist emphasizing his picture of the risks of the vaginal finger. To our mind the greatest (in fact, the only great) advance in childbed prophylaxis in many years is the development of rectal examination, yet some of our interns come to us completely unacquainted with this procedure, and many men who are doing only casual obstetrics will not take the pains to develop their judgment in this important item of diagnostic technique.

That bete noir of the obstetrician, the posterior position, is ever-occurring. With added years of observation, we find many suggestive symptoms in the labor when the case has not been clear on abdominal examination; both first and second stages are slow with varying pains, rectal examination shows persistence of the anterior cervical lip, which does not retract readily over the imperfectly flexed

head, and descent is sluggish. Encourage those patients, perhaps give them a rest with morphine and chloral and bromide, and allow them time for nature's effort at rotation, which is usually less damaging than radical interference.

We are doubtful that any method of support at the outlet is really valuable. After delivering several hundreds of Japanese primiparae with but rarely a stitch, and hundreds of whites rarely without one, we feel convinced that it is a matter of tissue rather than technique; and this opinion takes into account the relative size of mother and baby.

During the third stage we insist on *gentle* manipulation of the uterus, no abuse in the name of Crede. Also when the placenta is lying in the posterior vagina (as evidenced by the fundus, discharge of the retroplacental blood and slackening cord) it can be lifted out by tension on the cord much more safely and humanely than by driving it out from above.

The delivery of our women is largely in the hands of the general practitioner and will remain so. Therefore, an important factor in the "Rational Conduct of Labor" is the technical training of our interns in all the pathology of the maternity service. Since they are sent out at the end of their intern year, authorized to practice a branch of medicine that has such a proportion of true emergencies there should be no reservations on the maternity service. A breech in the hospital, under the eye of a chief, is much better experience than a breech later without help. All the complications of delivery and the puerperium should, with the assistance of the chief or assistant, contribute directly to the technical skill of the young graduate, leaving the specialist to annex as private assistant the young man who plans to limit his work and perfect himself in it.

G. Carl H. McPheeters, M. D. (Mattei Building, Fresno, California)—After reading and re-reading Dr. Fist's very interesting paper, I wish to say that I am in complete accord with the methods which he uses. For years I have employed the thorough physical examination for women before pregnancy, early in pregnancy, and examination of the expectant mother before labor begins. I never employ vaginal examination during the last month of gestation, but rectal touch only.

Care of the breasts of the primipara will well repay the physician, as well as his patient. We advise gentle finger massage of the entire breast to increase the circulation of the glands during the entire pregnancy. We advise traction of the nipples and the use of 10 per cent glycerite of tannin once daily, to toughen the nipples during the last month before the birth.

I especially approve of Dr. Fist's practice of keeping the patient quiet and having her avoid voluntary effort during the first stage. Many patients exhaust themselves by useless straining and bearing down during the first stage, and inertia develops during the second stage at the very time when voluntary efforts are necessary for normal birth. We also discourage the patient from walking about the room during her first stage. For the very nervous patient we employ codeine grains $\frac{1}{2}$ hypo. during the first stage, using morphine grain $\frac{1}{8}$ or $\frac{1}{6}$ for the very frightened and hysterical patient.

It is my practice to continue post-partum care for six weeks, and to examine every mother and baby at the end of six weeks. The ancient knee-chest posture and the hard ring pessary still have their field of practical use in preventing and correcting post-partum retroversions.

We have to thank Dr. Fist for a very interesting and practical monograph.

Slandering a Medical Man—To have and to maintain a good reputation is a matter of very great and serious concern to a physician, and he ought to give thoughtful and careful attention to the best means of protecting it against those who wantonly or wickedly seek to detract from it. Doctors are a frequent subject of gossip, but when it tends to damage them they should remember that it is not always defamatory, and that, indeed, they often derive substantial benefit from it. Ordinary foolish gossip should be altogether ignored, even though it be irritating and unfair, since by dealing with it seriously as a slander, wide publicity may be given to it and people may be led to infer that it is founded on something substantial when, as a matter of fact, it is mere irresponsible chatter.—*Medical Standard.*

AN UNUSUAL CASE OF PYLORIC STENOSIS

CASE REPORT

By ALANSON WEEKS, M. D., *San Francisco*, and
LEROY BROOKS, M. D., *San Francisco*

THIS case is reported because it is unusual, in that the child developed the disease, was operated upon and had recovered before the time it normally should have been born, and to emphasize again the value of surgery when it is indicated. We have not lost one of these babies in the last twenty upon whom we have done the Fredet operation. We repeat again the importance of early recognition and proper care, in order that these patients do not come to operation starved and dehydrated, as has been the custom too often.

K. W. entered Children's Hospital June 22, 1924, for Doctor Langley Porter. The following history, elicited from the mother, was typical of congenital pyloric stenosis, as far as the disease is concerned.

The boy was born May 18, 1924, two months premature, and weighed three and three-quarter pounds. He retained foods well at first and had normal bowel movements. He began to vomit his food on June 17, 1924. After that he regurgitated part or all of every feeding, regardless of what he was given. Vomiting for the last few days before entrance into the hospital was at times projectile in character. The stools became less frequent and finally he had none at all for several days. Enemas were returned with very small amounts of fecal matter. He was very much dehydrated and weighed only four pounds.

Inspection revealed the typical small lower and large upper abdomen of this disease. Definite peristaltic waves could be seen to pass from the fundus to the pyloric end of the stomach.

Doctor Porter elected to try thick feedings to possibly avoid operation, and at the same time gave fluids, both subcutaneously and intraperitoneally. The patient improved under this treatment for a few days, when he began again to vomit. The temperature was 101 to 102 daily, but the baby was some better because of the fluids. Doctor Porter advised operation, which was done on July 1, 1924.

The usual Fredet operation, as previously discussed by us in CALIFORNIA AND WESTERN MEDICINE, was performed.

The patient was given four ounces of 3 per cent glucose solution beneath the skin in the axilla and the groin before leaving the operating-room. He received a rectal drip of 3 per cent glucose and 3 per cent soda solution, which is our routine practice in all these cases, and Doctor Porter started the baby's feedings three hours after the operation, giving him first 3 per cent glucose solution and gradually working him back to his standard formula.

The baby had a hazardous convalescence, the temperature rising to 106 F. three days after the operation. This daily rise of temperature gradually subsided and the patient was discharged July 20, weighing five pounds, and was in excellent condition.

He was readmitted July 31, 1924, because the mother stated the baby had a cold. Since leaving the

hospital he had five or six normal stools per day. Upon readmittance his respirations were rapid, breath-sounds diminished in the right axilla, and there was diminished resonance over the right lobe posteriorly. X-ray showed pneumonia in the right middle lobe. He ran an irregular temperature from normal to 102 for ten or twelve days.

On August 8 he became very cyanotic. His pulse was about 60 and respiration shallow. He rallied from this attack after a few hours, and coughed up considerable rusty sputum which had a foul odor. After this attack he coughed considerably, and had other attacks of cyanosis, less severe, usually accompanied with cough and expectoration.

On September 5, fluoroscopic examination showed a pneumothorax of the right chest extending from the second rib to the diaphragm and filling the posterior two-thirds of the anterior posterior diameter of the chest. His attacks of cyanosis gradually decreased in number and he began to gain weight.

During his second stay in the hospital his abdomen would frequently become very greatly distended and a mass was discovered in the right inguinal region, which proved to be an easily reducible right inguinal hernia.

The patient was discharged the second time from the hospital on September 18, weighing eight pounds and two ounces and was in good condition. Doctor Porter tells us that he was in his office about October 11, and was in perfect condition.

We feel that this case is rather remarkable, in that it shows the surprising resistance of these little patients if they are furnished with plenty of fluids and glucose. Just why his temperature went to 106 three days after the operation is impossible to say. Doctor Porter feels confident that the pneumothorax was due to a suppurating mediastinal or bronchial lymph gland breaking through into the trachea or large bronchus. This would explain the symptoms of cyanosis and expectoration of foul material, as well as the pneumothorax.

It is very interesting that many of these little patients who were formerly operated upon are now cured by thick feeding. We believe that it is justifiable for the pediatrician to try thick feedings and supply the infant with plenty of fluids and 3 per cent glucose solution before an operation is advised. This would, of course, vary with the circumstances of each individual case.

There is no question that the thick-feeding treatment, if started early enough, prevents one-third of these babies from being operated upon. Our explanation of the action is that, because of the consistency of the thicker food, the hypertrophied muscles of the stomach are able to contract around it and force some through the pylorus like a bougie gradually dilating the canal, where more fluid foods are promptly shot back toward the cardiac end of the stomach.

We would like at this time to report in our series the second mother who has had two babies with congenital pyloric stenosis, both operated upon and cured. We some time ago reported another mother who had had four babies, three of whom had this disease, were operated upon and all three recovered.

EDITORIALS

PRACTICING MEDICINE BY MAIL

A situation which can be honestly defined only by calling it the practice of medicine by mail is becoming serious. Strong competition between magazines with large circulations, particularly those widely read by women and children, and *who use their mail order medical departments to get subscribers*, is changing what was formerly helpful health advice into the practice of medicine.

Some of these magazines not only advertise their medical departments conducted by mail, but through obvious sources secure the names of new mothers whom they bombard with circulars and other appeals to join their medical organization which they operate under one name or another. They do not stop at this, but go back to reports of marriage licenses and begin on the new bride and provide "all the health advice she needs." After the baby is born, she not only gets stereotyped medical service for herself, but for the baby as well.

Carefully and wisely prepared informative literature about health and disease given wide publicity is helpful and should be encouraged. Even wisely directed correspondence is deserving of commendation. But the highly commercialized and dangerous practice of medicine by mail as now being conducted by several extensively read publications ought to be condemned.

Several physicians who limit their work to the care of children have reported to us pathetic instances of the result of this sort of propaganda. Some mothers worry themselves sick trying to decide what to do as between the divergent advice and instructions of the family physician and that furnished from one to three or more magazines engaged in the practice of medicine by mail. One mother recently showed her physician three entirely different sets of instructions as to what to do for her three months' old baby with indigestion and vomiting. These instructions were from the "baby experts" of three different magazines, and were sent from an eastern city.

The pediatrician's greatest problem formerly was to neutralize the superstitions of "grandmothers." He thought this a hard problem, but it was nothing to that of the modern pediatrician in overcoming the fifty-seven varieties of unwise advice the present-day mother receives. The chief sources are from paternal government, national, state and local, from women's and children's magazines and other commercial enterprises, and by more personal contact with many varieties of technicians who often go beyond their legitimate field. These are some of the reasons for "forgotten" or delayed birth reports.

Many physicians, either of their own volition or by specific request of a mother, are not enthusiastic in providing "prospect lists" for the dozens of commercial influences that hover over the newspapers and government offices to secure promptly addresses of newly married couples and of births.

THE EFFECT OF MATERNAL SYPHILIS ON THE DEATH OF THE CHILD

Working under arrangements provided by the British Medical Research Council, Doctor Cruickshank has carried out a series of carefully conducted observations in Glasgow to determine the influence of maternal syphilis on child mortality.

From 9 to 10 per cent of unselected mothers from a general hospital service gave positive Wassermann reactions. These figures correspond to similar ones from other centers. They are, of course, somewhat higher than they would be among the population in general. In 94 per cent of the Cruickshank series, the Wassermann reaction in the child at birth corresponded with that of the mother.

One striking result of the study was that the percentage of abortions due to death of the fetus was apparently no greater among syphilitic mothers than others. Stillbirths, however, were 18 plus per cent among syphilitic mothers as against 15 plus per cent among others. The incidence of premature births was 32 plus per cent among syphilitic mothers as against 19 plus per cent of others. Among those children who could be followed up, it was found that the infant mortality was considerably higher among the infants of syphilitic mothers.

This group of infants and young children help to swell the lists of those diagnosed as "malnutrition" and "anemia" by inadequate methods.

The most interesting feature of Cruickshank's work is that, by the most painstaking studies, he confirms the conclusions arrived at by others.

DOCTOR, HEAL THYSELF

Doctor, is your health good? How do you know it is? Do you practice what you preach by having your own periodic medical examinations?

The chances are that you don't. The chances are nine out of ten that a careful examination by one of your colleagues would uncover one or several conditions that you ought to have remedied and which if left alone may cause serious harm. You know this to be a fact. Then why do you procrastinate? Isn't the answer precisely that which is applicable to other citizens? It is, and this explains why it is not more health education most of the world needs, but more gumption. *The knowing and the doing about health or any other question are two different things. The doing is the one generally neglected.*

A person of moderate intelligence who makes a practice of *doing* has a far greater chance of living longer, happier, and more usefully than has the best-informed physician who *knows*, but *does not*. **Think it over, doctor, and either be a doer about your own health or don't complain about your patients who know because you told them so, but who fail to do for precisely the same reasons that are applicable to yourself.**

The Pennsylvania Medical Association is trying to persuade its members to have medical service of the kind its members are advising their patients to have. It is providing the service.

They have arranged to offer examination service to members as one of the features of their annual meetings, notes the editor of the Atlantic Medical Journal. "Twenty of the leading physicians of the

State and County Medical Societies, Attention

THE HOUSE OF DELEGATES OF THE AMERICAN MEDICAL ASSOCIATION PASSED THE FOLLOWING VERY IMPORTANT RESOLUTION AT THE 1924 SESSION:

"WHEREAS, PERIODIC MEDICAL EXAMINATIONS OF ALL THE PEOPLE FROM BIRTH TO DEATH ARE OF GREAT IMPORTANCE IN THE PROMOTION OF HEALTH; THEREFORE, BE IT

"RESOLVED, THAT STATE AND COUNTY MEDICAL SOCIETIES BE URGED TO ENDORSE AS A PART OF THE HEALTH PROGRAM OF ORGANIZED MEDICINE THE MAKING OF THESE EXAMINATIONS:

"THAT THE MEMBERS OF THE RESPECTIVE SOCIETIES BE REQUESTED TO MAKE SUCH EXAMINATIONS IN THE HOMES OR IN THEIR OFFICES, FREE TO ANY PERSONS, WHO, BY REASON OF ECONOMIC CONDITIONS, REQUIRE SUCH FAVORABLE CONSIDERATION, AND

"THAT IN THE PERFORMANCE OF THE WORK THE SAME SYMPATHETIC, CONFIDENTIAL RELATION BE MAINTAINED BETWEEN PHYSICIAN AND PATIENT OR FAMILY AS HAS EVER CHARACTERIZED THE EFFORTS OF TRUE PHYSICIANS."

state have consented to make these examinations. Each will be made in the office of one of the doctors in Reading. The result of the examination will be entirely confidential. The doctor volunteering must think he is well. He will send his name in to the secretary as a volunteer. He will receive a history blank, which he will fill in, putting thereto an examination of his urine, bearing on protein, specific gravity, sugar, roughly total 24-hour quantity. He will receive an appointment from the doctor to whom he is assigned, with a given date and hour, preferably on the first day of the meeting, the street and office number being set forth.

"This examination will be made at a given date and hour, and thereafter the examiner and the one examined will have a brief consultation as to how the examination could be bettered, as to how the history blank could be improved, as to how best this whole subject can be put to the profession in such wise that it will be generally adopted. The one examined will have excluded, insofar as this can be done, a hidden menace to his health. He will have demonstrated a method of examination which he is free to criticize. He will get home better prepared to carry out the general policy."

The only difficulty about the service is that of persuading the doctors to avail themselves of the opportunity.

Is it more "education" or more "gumption" that is needed?

MORE MAIL-ORDER DOCTORS

A non-medical concern, with headquarters in Chicago, is circularizing citizens and inviting paid membership in their longer living, stay well, periodic health examination, medicine by mail, plan. Their advertising matter forms a basis of inquiries from readers of Better Health Service and from both doctors and their patients. A San Francisco business man recently received a batch of this propaganda and turned it over to his physician (Harry Alderson), who in turn forwarded it to CALIFORNIA AND WESTERN MEDICINE for comment. The organization in question claims to be the original one in the personal practice—for a fee—of preventive medicine and life extension by periodic health examinations.

There is a "medical director," and emphasis is

placed upon the fact that he is a member of the Illinois Medical Association and the American Medical Association. He is presumably, therefore, an educated physician licensed to practice in Illinois. The advertising literature is not overly specific as to just what are the duties and responsibilities of the "medical director" in supervision of the laboratory work and in making the "copyrighted explanatory key and helpful suggestion" so "confidentially" supplied to the patients.

The propaganda is specific when it says: "*Our medical director gives on each report personal remarks upon your physical condition, and while we do not treat nor diagnose, we are always willing and ready to help our subscribers by writing a personal letter, advising them of the significance of the findings.*"

Again, in discussing the great value of the California patients' records in the central office in Chicago, the propaganda says that "*reference to them so often enables our medical director, in his comparisons, to note approaching trouble in time for it to be corrected by the simple means suggested in our reports.*"

This health-by-mail service, consisting essentially in a quarterly urine examination of old specimens sent by mail to Chicago, claims that only 5 per cent of 5000 patients had normal urine and that 2223 "subscribers" (patients) were "made normal" (cured) "through attention to our helpful suggestions." The patients of this medicine-by-mail organization are said to reside in all parts of the United States and Canada. The claim is also made that physicians endorse their SERVICE "when they understand there is no treatment connected with the bureau." Immediately following this sentence is a statement of a physician to the effect that "health insurance is coming and . . . the medical profession might just as well make up their minds to swallow it."

After all, "there is more than one way to skin a cat."

CHECKING UP ON DIAGNOSES

It is good for all of us to occasionally have a check-up on the reliability and accuracy of our diagnoses. This is best done by comparing clinical diag-

noses with autopsy diagnoses in a large series of cases.

The best, most complete and most significant study of this kind yet made is that recently reported (Journal of the Philippine Islands' Medical Association) by A. G. and A. B. M. Sison of Manila. Conditions were particularly favorable for the study. The medical college, hospital research laboratories, and city morgue are all upon the same campus. They are all operated under one administrative authority. The records of the college and hospital are unusually complete, well co-ordinated, and the faculty of the school is ex-officio the staff of the hospital, both administered by a dean and director. A far-reaching weekly clinico-pathological conference was instituted many years ago and has continued to function. Practically all patients who die in the large hospital go directly and promptly to the department of pathology and the complete sealed clinical record goes with the body. Autopsy is carefully done and tissues and cultures promptly worked up. The findings and such specimens as are significant are preserved until the next weekly meeting of the clinico-pathological conference.

At the conference a brief clinical report is made, followed by the report, with demonstration of specimens by the pathologist. The results are always interesting, often stimulating, and sometimes depressing. All physicians are invited to attend these conferences and many accept. All medical students, interns and house officers are required to attend, and many members of the faculty are always present. It was from material handled in this way for years that the Sisons were able to compile their report.

Of the more than 10,000 complete clinical and post-mortem records available, the authors selected only the medical cases. As has long been the custom in that splendid service, each *diagnosis* is entered. The average patient having from two to ten clinical diagnoses just as they have several anatomical diagnoses. In Sison's medical cases, there were 2282 clinical diagnoses and 3046 anatomical diagnoses in the same bodies.

THE FINDINGS

In the series of 3260 diagnoses there were 526 errors of commission; in the clinical diagnoses, 848 errors of omission; 1886 correct diagnoses.

Divided somewhat by systems, the percentages of error were as follows: Errors of commission, 16 per cent; errors of omission, 25 per cent; correct diagnosis, 58 per cent.

Further appreciation of the value of this work is made by including comparable figures from Cabot's report of the Massachusetts General Hospital cases some fourteen years ago along the same lines:

	Massachusetts General Hospital Per cent	Philippine General Hospital Per cent
Circulatory diseases	34	35
Respiratory diseases	45	38
Urinary system	53.3	54
Digestive system	43.6	36
Nervous system	31	58
Miscellaneous	6.5	33

The striking differences in the findings in the two series under headings of "miscellaneous" and "nervous system" are explained in the article. The rea-

sons are not of a kind that reflect unfavorably upon anyone's work.

THE WORK OF THE ROCKEFELLER FOUNDATION

The annual report of the Rockefeller Foundation sketches such an amazing volume and variety of activities that a reviewer can note only a few of them. Few people realize the far-reaching and rapidly growing influence of this immensely wealthy foundation, nor the ramifications it is making into many phases of the social and health structure of civilization. Few will question the motives of the trustees of this vast private fortune, and all will applaud most of the things they are doing.

Some have, more do, and many will in future hesitate to endorse *all* of their *methods* and may even question the judgment of the trustees in certain particulars. This, of course, is unavoidable in any enterprise, and it is particularly true of those who serve the human race in the broad fields of health.

Physicians will be interested in the apparent effort of the Foundation to split the profession of medicine into two professions: "The idea that an ordinary medical education fits a doctor to be a health officer is a serious error which does much harm. He needs additional graduate training for what is recognized as a special profession," says President Vincent in his annual report.

The report outlines as among the "most important and fundamental duties" of a county "Health Officer"—"demonstrations in sanitation, the provision of a pure supply of water and milk, medical inspection of school children, organization of *maternity and infant welfare centers*, and the creation of centers for suitable care of such diseases as tuberculosis, trachoma, the venereal trio, and for the correction of remediable defects in children . . . and he will have to study his field so as to be prepared to give advice to the *INDIVIDUAL*." "There were, at the end of the year 1923," says President Vincent, "230 counties in twenty-eight states of the United States with full-time health organizations. The number grows each year, and a few counties which have given the system a *trial fail to continue it* and to expand the unit to meet the more obvious needs of the people."

When each of the some three thousand counties of the United States has a well-paid, full-time "Health Officer" who is even an educated licensed Doctor of Medicine we will have made the most important step in public health now confronting our people. When each of these full-time public health physicians has added to his staff sufficient nurses and administration force, another long step will have been taken which none now living is likely to live long enough to see accomplished.

During the development of these plans, we hope to see the schools of public health turn out more specialists who will have the ability and the tact to become leaders in our many great centers.

When the people have been educated to appreciate and *finance* even these expensive movements, it will be time enough to say that "the day is passed when any physician qualified for practice can act as health officer."

With full appreciation of the vast, wonderful and

praiseworthy work the Rockefeller Foundation is doing so well in so many ways and admitting the fine motives that we are ready to believe activate the trustees of the Foundation, many physicians and other persons nevertheless feel that they are delaying the consummation of some things much to be desired by methods that are at least immature.

WHAT'S THE MATTER WITH THE COUNTY SOCIETY?

Now and again—with increasing frequency of late—there comes notification of the organization of an independent medical society, a physicians' "club," or of the creation of some sort of association of physicians already members of a county medical society. The announcement of one of these, recently organized, stated: "The idea primarily guiding the establishment of such an organization is one which aims at developing greater social intercommunication and better human relationship among members of the profession." What's the matter with the county medical society in that bailiwick?

Another independent organization announced its birth into this overorganized world with a statement to the effect that it was intended to bring about a better understanding among members of the profession and its community, with respect to their social and professional privileges and obligations, and to create firmer friendships and more constant and effective general co-operation between its members; but more particularly to give better opportunity for them to help each other to become better qualified as practicing physicians. What's the matter with the county society in that bailiwick?

What is it that these purely local medical groups can do that the county society cannot do? Just what is the matter with the county society within whose jurisdiction independent organization is being effected by its own members? It may be that a careful investigation into the situation by its officers will discover something wrong and that a little careful study will result in correction, to the end that the need for new non-affiliated organizations will quickly disappear. Incidentally, the district council might help some. —American Medical Association Bulletin.

"IN TWENTY-EIGHT CASES THE PATIENTS WERE—"

I have just completed the editorial examination of three articles submitted for publication in CALIFORNIA AND WESTERN MEDICINE. Improper and even stupid use of "case" or "cases" was corrected in over fifty places in the some 12,000 words contained in the three articles.

Instances like the above heading, where the author goes out of his way and adds useless words to his article apparently solely in order that he may use his beloved word "case" are extremely common in many, many manuscripts.

The "treatment of cases"; the "death of cases"; the "improvement of cases"; "the early stage of cases"; and scores of similar faulty uses of this word by writers who know better contribute a tedious and trying problem to every medical editor.

"Case" and "cases" are perfectly good words when properly used; but they neither die, get well,

nor do many of the other things they are charged with. "*Case*" is not synonymous with "*patient*."

I do not pretend to be a stickler for excellent English, and believe in granting to everyone the right to use words, as he does methods, as his servants. *But there are limitations beyond which no one should go.*

MEDICAL HISTORY

The May number of CALIFORNIA AND WESTERN MEDICINE will be devoted largely to articles about the history of Medicine—particularly California medicine.

Doctor Hans Barkan, secretary of the Pacific Coast Society for the Study of the History of Medicine and the Natural Sciences, has assumed co-editorial responsibility for the number. Several articles are already in hand, and arrangements have been completed for others. Doctor Barkan, 516 Sutter street, San Francisco, welcomes suggestions, notes or short, carefully prepared articles upon any phase of California medical history, provided they are in his hands before March 1.

We are particularly anxious to have a copy of "A History of the Medical Profession of Southern California," written some years ago by George Kress. Any reader who may have a copy will assist us by loaning it to our office.

A FREQUENT FAULT OF MEDICAL WRITERS

A recent article in a medical journal opens with this statement: "Diet in pregnancy has been given too little attention by the medical profession, and even obstetricians do not, as a rule, scientifically determine the composition of the patient's diet, as to caloric value, and relative carbohydrate, fat, and protein content."

Further on in the article the author says: "As one endeavors to lay out a diet for the pregnant woman, it becomes apparent at once that there can be no routine diet for pregnancy. Intelligent management demands that each patient receive special attention. For some patients there need be no modification from the usual diet, while for others very rigid restrictions must be made."

It is often stated that one of the reasons for writing a medical article is to bring the author's conclusions, and incidentally the author, to the attention of his colleagues. *Why then open an article, as so many do, with a criticism of doctors and thus invite the reader's resentment as many writers do?* The above quotation is chosen because the criticism is exceedingly mild compared with that in copy as most editors first see it.

One of the most difficult and inexcusable problems every medical editor has to solve is to delete from medical manuscripts, or render innocuous, criticisms of physicians, usually unwarranted.

WE WISH TO MAKE A PLEA TO OUR AUTHORS TO SAVE THE EDITOR TIRE-SOME WORK AND ENHANCE THE VALUE OF YOUR CONTRIBUTIONS BY OMITTING CRITICISM OF FELLOW PHYSICIANS FROM SCIENTIFIC ARTICLES. IF AN AUTHOR WISHES TO CRITICIZE AND WILL DO SO IN A SEPARATE LETTER OR ARTICLE WE WILL PUBLISH IT IF IT IS NOT LIBELOUS.

Medicine in the Public Press

"Mental Menopause"—This new slogan invented by a "psychologist" is being used as the latest fad in defending criminals.

It is said that an alleged murderer is suffering severely from this "Alzheimer's disease" or "mental menopause," and that his attorneys are putting it forward as the reason for acquittal and as the explanation for the philanthropic propensities that led up to the murder.

Quite a catchy slogan. If the law recognizes the disease (?) we may look forward to another new line of clinics.

To License Child-bearing—Hornell Hart, Professor of Social Economy at Bryn Mawr College, Pennsylvania, is quoted as saying that: "Chauffeurs are licensed, a plumber is not allowed to meddle with your house-drain unless he is licensed, and a doctor cannot prescribe for your children's ills unless he has spent years in study and received a license. And yet so vital a matter as the bringing of children into the world is practically without regulation or legal restraint."

The time has now come, Professor Hart insists, to apply intelligence rather than sentiment, and go one step further and *require every married couple to get a license before they bring a child into the world.*

Hart foresees the day when each marriage license bureau will have on file an up-to-date list of the mentally deficient, just as the police departments have records of criminals.

The Marriage License Bureau is about the only government agency left that does not find some excuse for conducting a "clinic." This will provide them with the excuse.

It will be a "busy clinic," and we presume a "free" one. Think of all the jobs for "doctors" who must carefully "survey" both the man and woman before marriage. Then when they decide after marriage that they want children, they must get another license from another department of the clinic before making efforts to bring one into the world.

What about the bootleggers in child-making? There are plenty of them in this field now, and their "goods" appear quite serviceable, even though they are citizens under disguised labels.

Therapeutic Thaumaturgy—Under this title, Arthur J. Cramp of the American Medical Association Council on Pharmacy and Chemistry tells a story (*American Mercury*) about medical frauds that every doctor will appreciate.

Freeing Mankind From Disease—Under this title, Doctor W. W. Keen, the most universally beloved and most widely honored of living physicians, tells (*Collier's*) what he calls the "amazing story" of modern accomplishments in the world's campaign for better health. Every physician and other health worker, as well as other intelligent citizens, should read this stimulating, encouraging, helpful message. It is told in the simple, clear, convincing style that ever characterizes the worthwhile message.

Is This a Just Criticism?—A professor in a public health school which invites physicians as students, in discussing certain phases of parasitism (*Scientific Monthly*), makes this unnecessary and uncalled for criticism of physicians: "The physician, usually knowing nothing of parasites except the symptoms which some of them produce in human beings, is, of course, prone to believe that the injury of the host is an essential property of a parasite, and to declare that even when we can see no injury one must nevertheless be present."

Another "New Cure" for Cancer and Baldness—Several newspapers published a story sent out from the Radiological Society of North America, meeting in Kan-

sas City, to the effect that the ultraviolet ray would "cure" baldness and cancer!!

The essayist is quoted as having said that the ultraviolet ray "would grow a fine outfit of hair on a head as bald as a billiard ball." And what it wouldn't do to cancer—Oh boy!

The story had such a familiar ring that most editors refused to run it or sent it to the advertising department for consideration as paid space. One paper published part of the story as the doings of the Radio Logical Society. That editor has a sense of humor.

A Prophet and His Own Country—News dispatches announce the arrival in New York of a French doctor with a new "sure cure" for pneumonia. The "doctor" is quoted as saying that "Pneumonia is really not dangerous at all." "And certainly there is no reason for its ever being fatal." "Even persons in the last stages can be cured, as if they had nothing more than a bad cold."

Some editors evidently sent this propaganda to their advertising departments, and others published it as "news"! Any doctor who had a cure of the kind described would not have to leave Paris and come to the United States for patients.

If Benjamin Franklin Came Back Today—"Benjamin Franklin died in 1790—134 years ago. Could he return to make appraisal, what wonders would confront his astonished vision, what triumphs of the Fifth Estate compel his admiration!" says Arthur D. Little (*Atlantic Monthly*). "The Fifth Estate being designated as 'composed of those having the simplicity to wonder, the ability to question, the power to generalize, the capacity to apply.'"

"In great hospitals, permeated with the scientific spirit and equipped with many new and strange devices for the alleviation of human suffering, he would hear of the incalculable benefits which medical and surgical science have conferred upon mankind. He would see the portraits and listen to the story of Pasteur and Lister and Loeb and Ehrlich. We know today with what joy and relief the world would welcome a veritable cure for cancer, but we can little realize the emotion with which one like Franklin would learn in a single afternoon of the germ theory of disease, of preventive serums, of anti-sepsis, of chemotherapy, of the marvelous complexity of the blood stream and the extraordinary influence and potency of the secretions of the ductless glands. What appraisal would he make of the service to humanity which, in little more than a generation, has mitigated the horrors of surgery by the blessings of anesthesia and anti-sepsis, which has controlled rabies, yellow fever, typhoid fever, tetanus, which is stamping out tuberculosis, curing leprosy, and providing specifics for other scourges of the race? What values would he put on insulin, thyroxin, adrenalin? The physician is no longer compelled to rely on herbs and simples and drastic mineral compounds of doubtful value and uncertain action. Compounds of extraordinary potency, isolated or synthesized by the chemist, are now available to allay pain, correct disorders, prolong life, and even to restore mentality and character."

Shall We Have Health?—Under this title, a San Francisco newspaper is conducting what it pleases to term a "New Kind of Health Column." It is. It is essentially a criticism of "orthodox medicine," calculated to undermine the confidence of the sick in the ministrations of healing, consolation and mercy, as carried out by their physicians. The author of the column wishes to bring back into "full play the only remedial agent known to true science—The Healing Force of Nature—the vis medicatrix naturae of the ancients."

We wonder what killed people and killed them at much earlier ages than now in those good old days of "vis medicatrix."

Where the Highest Skill is Needed—The medical service required in making periodic health examinations is of a high order, in that it requires not only time, but also discriminating judgment rightly to interpret the significance of various minor findings in relation to habits of living.—Anna Richardson (*Medical Times*).

Secretary and Associate Editor for California

MEMBERSHIP DUES

The membership assessment of the California Medical Association and of your County Society is now due and payable. Delinquency is as of March 1. Non-payment after that date debars a member from participation in the state program, from holding office, and from the receipt of CALIFORNIA AND WESTERN MEDICINE until reinstatement. Many members carelessly let their membership lapse and, upon reinstatement, write for the omitted numbers of CALIFORNIA AND WESTERN MEDICINE. In very few instances has the secretary's office been able to comply with such request.

The California Medical Association dues for 1925 were fixed at \$10. The prompt payment of this sum, together with your county assessment will obviate later grief.

1925 SESSION C. M. A.

Reservations—Reservations for the 1925 session will be handled by the Yosemite National Park Company direct, and will be opened as of March 1. For the information of those who have not attended a Yosemite meeting, Yosemite Lodge will be convention headquarters.

Various kinds of accommodations are available. Rooms in the Sentinel Hotel and also detached redwood cottages with bath, both in conjunction with meals in the main dining-room, can be had on the American plan at the rate of \$8.50 per day. Redwood cabins and rooms in the Sentinel Hotel without bath, and with meals in the main dining-room are furnished at \$6 per day. Canvas cabins without bath are \$2 per day. Meals in the cafeteria average about \$2 a day. It is obvious that the cost of attendance on the convention may range between \$4 and \$8.50 per day.

When a reservation is made with the Yosemite National Park Company, the applicant is sent a questionnaire, asking for definite instruction as to the kind and cost of room desired, the duration of his stay, the date of arrival and the number in his party, and the route by which he expects to reach the valley.

This office would appreciate a full and prompt reply to this questionnaire, as from it our registration cards will be made out. Each member will be indexed by his county and name before his arrival, and the tiresome and annoying delays incident to the usual registration obviated. The registration desk will be at the extreme left-hand of the main porch of Yosemite Lodge. Every member should report there immediately on arrival. The number of his assigned room and his ticket to the dining-room or cafeteria will be furnished him at that desk. His luggage is in the baggage room immediately adjoining

the registration desk, and boys will be on hand to show him to his assigned quarters.

Program—Section officers report active progress on the meeting program. On February 15, the program closes. All members who desire to present papers should secure a place on the program before that date.

THEODORE RETHERS
1867-1924

The death of Doctor Theodore Rethers recently is a distinct loss to the medical profession of San Francisco and California. His passing is a greater loss to his many friends and patients whom he served so skilfully during his lifetime.

Doctor Rethers was a man of exceptional scientific and mental attainments which, combined with his great simplicity and sympathetic friendship, made him a most human doctor and loyal friend. His skill as a surgeon is known to the physicians, and needs no added tribute at this time.

The funeral was a notable outpouring of all classes of people, and the eulogy pronounced by his lifelong friend, Monsignor Joseph Gleason of Palo Alto, was one of the most eloquent tributes ever heard by the friends of Doctor Rethers and the professional men who attended the obsequies.

Doctor Rethers was born in San Francisco June 28, 1867. After attending the public schools he went to the University of California, leaving there in 1885 to study medicine in Germany. He obtained his degree magna cum laude in the University of Berlin.

Returning to San Francisco in 1892, he began the practice of his profession. In the following year he was appointed a member of the San Francisco Insanity Commission, a position which he retained for thirty-one years.

In 1898 he went with the First California Volunteers

as regimental surgeon to the Philippines, remaining with the Army until the end of the Spanish War. Later on, during the administration of Governor Johnson, he was appointed surgeon-general of the National Guard of California.

For the past fifteen years, Doctor Rethers was surgeon-in-chief of St. Mary's Hospital of San Francisco. It is said of Doctor Rethers by Doctor John Galloway and others that, more than any other doctor and surgeon, Rethers gave assistance, advice and professional help to the younger members of the profession.

In 1896 the Doctor married Annie O'Kane, the daughter of a pioneer San Franciscan. He is survived by his widow and six sons—Theodore, Frank, Harry, Edward, Charles and Robert, and a brother, Colonel H. F. Rethers, U. S. A.

EULOGY PRONOUNCED AT THE FUNERAL SERVICES BY
MONSIGNOR JOSEPH GLEASON

"We are assembled to do honor to the memory of Dr. Theodore Rethers, a public-spirited citizen, a true friend, a devoted father of his family, a veteran surgeon of the Spanish-American War, a recognized leader of the medical profession in California. His life was an inspiration to us all. It was my privilege to know Dr. Rethers from childhood. From his earliest days he had the faculty of making friends and holding them. He never from his youth took up a problem that he would not see through to the finish, and this characteristic of work and thoroughness characterized his entire career. He was noted for this during his university course and his professional studies in Europe. When, therefore, after his return to California, he began his career as a young doctor, it took but a very short time for him to obtain recognition. By unremitting study he kept abreast of scientific advances and he was accorded a position of leadership, particularly from the members of his own profession.

"He was a man, however, who had not merely the technical knowledge and skill of the accomplished physician and surgeon, but he had with it that Christian character which always ennoble the physician. I never met a man who had a higher regard, not for the mere dignity, but for the actual sanctity of his profession. There are two great mysteries of human life, our entrance into and our exit from the world. At these the physician presides. He welcomes the new born babe, he bids Godspeed to the dying. It is a very easy thing for a physician to become so familiar with the technique of his profession in handling the human body to forget that that human body is the temple of God. The physician and surgeon who forgets this, and callously ignores the divine mystery of life, is very liable to become little more than a cold blooded mechanic or an artistic carver. The real inspiration of the physician and surgeon's professional life is the recognition of the fact that he is handling the work of God. Dr. Rethers never allowed his skill as a surgeon or his long practice in his profession to breed that familiarity which fathers contempt. And the reason of it was that Dr. Rethers was a man of faith—he believed in God—and that faith guarded him and guided him. This may explain to a certain extent the remarkable trust that his patients always had in him. He was their friend. Rich or poor, black or white, there was no distinction, every man who ever was his patient remained his friend. He was devotion itself in his attendance. The relation between the physician and his patient is very parallel to the relation between the priest and the penitent who comes to confession. Both priest and physician are custodians of the secrets of the soul. They must have the faculty of inspiring confidence and they become confidants whose sacred trust can never be broken. On this account the role of physician was to Theodore Rethers almost sacramental in its sanctity.

The physician and surgeon are supposed to lead a life of self-sacrifice. He actually did live that life of self-sacrifice. There was no doctor who more heartily abhorred the necessity of a monetary compensation for his services. From my own personal knowledge he had a large clientele from whom he could never receive any returns.

Dr. Rethers was endowed with the sense of humor. There is no question but that this is a real gift from

God. The man who can laugh will find it a very easy matter to save his soul. There was a merry twinkle in the eye of Dr. Rethers that spoke the joy of his soul and kept his friends in good humor. It was a tonic to his patients. It served to bridge him over two or three severe crises in his own life for it was not all smooth sailing in the long years of his professional career and when difficulties did come, his faith in God and his sense of humor saved the day for him.

"Privileged as I am today in speaking over Dr. Rethers, I am prompted to recall a little incident in the life of St. Paul that the ordinary reader might gloss over. St. Paul, convicted in Syria, appealed to the Supreme Court of the Roman Empire. When the time came he was shipped on a Roman transport and sent on to the Capital. Under the Roman law even an officer's wife could not go with him on the transport. There was only one allowed to accompany a prisoner and that was his personal slave. St. Luke, who wrote the third Gospel and who was the companion of St. Paul in his missionary journeys, was likewise a physician. He was devoted to St. Paul and when the Apostle was shipped on the transport, St. Luke, the physician, took advantage of the one loophole in the Roman law and signed up as the slave of St. Paul. It always comes before me as an example, not merely of personal fidelity, but of the devotion of the physician. That same St. Paul, when he wrote from his prison in Rome to his friends in Greece and Asia Minor, spoke of all his companions leaving him, one after the other. How human it is to read that little line of his where he says, 'they have all left me, all except Luke, my beloved physician.' This warm relationship between physician and patient was always the characteristic of Dr. Theodore Rethers.

"From childhood I knew him in the thoroughness of his study, and in the integrity of his character. It was my privilege years ago to officiate at the ceremony which united him and his bride. I have seen him develop, with the highest recognition in his profession, and I always found him the same—quiet, unassuming, good-humored, devoted and self-sacrificing. He lived and died a credit to the medical brotherhood of California. All of them will miss him, but he will be held in particularly grateful remembrance by the army of young physicians whom he guided and helped in the first difficult steps of their career. He was the friend of all, but especially of the young doctor.

"Gathered in this sacred edifice, please do not forget that Dr. Rethers was a sincere Christian believer. He understood and appreciated the Catholic philosophy of life and death. He would remind you, if he could speak from his casket today that we have come here not to honor him with empty words. He has finished his term of probation here in this world and the good God has beckoned him through the gate of death. At this solemn Sacrifice of the Mass, the holiest act of the Catholic religion, we are assembled for a nobler purpose and that is to say a prayer for the repose of his soul. Common ordinary decency develops charity in the heart of man. Like all decent men you feel that a man who will not reach out a sympathetic helping hand to one in distress is beneath contempt. And because we believe in giving a helping hand to the living, it is very easy to understand the Catholic practice of extending our charity beyond the grave and saying a prayer for the repose of the dead who can no longer help themselves. That is why we are here today. If it were simply a matter of doing civic honor to the memory of Theodore Rethers, a few words and a quartet in a public hall would cover the program. On the contrary, all of us are assembled today as friends of the dead doctor for the specific purpose of doing for him, what he, as a Christian believer, would do for you if one of you lay in that casket today. No matter what might be your religious belief, he would give you the best that his Catholic religion afforded him under the circumstances, namely, a prayer for the repose of your soul. That is what I ask of you now. Unite with me in saying within your hearts these words: 'Forgive him, Oh Lord, for any mistakes he may have made. He was human but he was thy faithful servant. Remember his good deeds and blot out the chance error. Eternal rest grant unto him, Oh Lord, and let perpetual light shine upon him.'"

LUTHER MILTON POWERS, M. D.
1853-1924

Doctor Luther Milton Powers, for thirty-two years Health Commissioner of Los Angeles, died October 31, 1924.

He was born in New Hanover County, N. C., April 5, 1853, attended Wake Forest College, North Carolina, and was graduated from Washington University School of Medicine in 1877. After post-graduate study at Bellevue and the College of Physicians and Surgeons of New York, he practiced medicine at Plymouth, N. C., until 1886. Then, after a year in Nebraska, he came to Los Angeles. Doctor Powers is survived by his widow, Mary R. Powers, two daughters, Mrs. Anne Powers Keller, Miss Lucy Powers, a son, William, and a grandson, Milton Powers Keller.

When the history of the last three decades of Los Angeles is written by impartial observers, the work of Luther M. Powers will be so outstanding that he may be easily awarded the honor of being our most useful citizen. In the delirium of his last hour he called upon those about him to save the children from diphtheria, showing that the "ruling passion is strong in death."

WILLIAM DUFFIELD.

Los Angeles County Medical Association Honors Doctor Powers' Memory—WHEREAS, The death of Doctor Luther Milton Powers, Health Commissioner of Los Angeles for almost a third of a century, should cause, and does cause, this society and our profession to pause and meditate upon the work of a most useful citizen and physician, and to honor his work and the good name he has left among us.

The study of the life of Doctor Powers is a study of the evolution of modern scientific sanitary medicine, for his connection with the Los Angeles Health Department goes back to the time when that which is now considered basic in public health work was in its beginning. Through study, travel, and association with leaders in the thought of the time, he became an authority in sanitation and public health. He built our health department from a service of two men to a great department with sixteen divisions employing several hundred men and women in its various activities.

He was in advance of his day in organizing a bacteriological service, and he was one of the real pioneers in the crusade for pure milk and in the establishment of milk commissions. The remarkable working efficiency of the department was demonstrated just at the time of Dr. Powers' death by the instant recognition of pneumonic plague and its annihilation within ten days of the onset.

No more efficient public health service was ever given in a grave emergency at any place.

Dr. Powers was past president of the Los Angeles County Medical Association. He served on the Board of Councillors for many terms, where his service was most valuable, because of his wide acquaintance and good judgment. His whole life and work were in and for organized medicine, and no man ever served the profession and the public more faithfully, more loyally, nor more unselfishly.

In view of the great service rendered to mankind by Luther Milton Powers, it is hereby

RESOLVED, That a tablet of bronze be placed in a conspicuous place in the County Medical Building, recording the distinction of his service and the high esteem in which his name is held.

RESOLVED, That one scientific program, devoted to public health and sanitation, be given each year in memory of Doctor Luther M. Powers and Doctor Stanley P. Black, two outstanding pioneers in public health medicine.

RESOLVED, That the sympathy of this society, with the expression of our highest esteem, be extended to the bereaved family of Doctor Powers.

F. C. E. MATTISON.
ELMER R. PASCOE.
WILLIAM DUFFIELD.

FRIEDRICH FEHLEISEN, M. D.
1854-1924

(Eulogy by the San Francisco County Medical Society)

In Doctor Friedrich Fehleisen, the San Francisco County Medical Society has lost a member whose name is known wherever medicine is taught. His work will live after him, but so modest and devoid of pretentiousness was he that not many of his younger colleagues knew by name the upright and austere figure that used to sit at the back of the medical meeting room, quietly and attentively, often it seemed, pensively and reminiscently listening. Not many of the younger men to whom he listened knew that this was Fehleisen, the discoverer of the streptococcus of erysipelas. And as he would get up and stride solitarily and silently from the meeting, he

seemed to carry with him the shades of other hours—of V. Bergmann's clinic, of attendance upon emperors; and his mind to muse upon the vagaries of Fate and the determination of life by the whims of kings.

Friedrich Fehleisen was born on the 20th of April, 1854, in Reutlingen, Germany. His father was Doctor Friedrich Fehleisen. He studied at the Universities of Tübingen, Strassburg and Würzburg, and took his degree at Würzburg in 1877, with a dissertation "On a Case of Aphasia." For many years he was V. Bergmann's first assistant and head surgeon of the surgical clinic of the University of Berlin. He left Germany in 1895, taught for a short time at Washington University, but soon followed an invitation of Doctor Vowinkel of the California Women's Hospital to visit him. He remained to make San Francisco his home, and succeeded Doctor John F. Morse as chief surgeon to the German (now the Franklin) Hospital in the same year—1895.

Fehleisen married Fraülein Marie Herdtmann in 1890. He leaves two children. His wife was one of two German nursing sisters chosen by the Empress Frederick to learn English nursing under Florence Nightingale. She returned to V. Bergmann's clinic after a course at St. Thomas' Hospital in London. Finding it difficult to get volunteers for the diphtheria ward, she volunteered for this duty herself, and there first met Fehleisen.

Fehleisen died suddenly on the 28th of August, 1924, of heart disease.

His fame will rest on his discovery of the germ of erysipelas; he also made pioneer research into the influence of streptococcic infection on malignant tumors.

Germany was unfortunate to have lost this man, but we were the gainers. The memory of his person and the influence of his work, which fell at the beginning of the constructive period of San Francisco medicine, remain ours; and ours is the figure of this earnest, modest, and upright surgeon.

OSWALD H. BECKMAN, M. D.

1851-1924

It is with great regret that we note the loss of one of our members, Dr. Oswald H. Beckman, who died at his home in Glendale, November 28.

For fifteen years he followed his vocation in Fort Bragg, Mendocino County, where he owned and managed Beckman's Sanatorium.

As secretary of the County Society, he devoted himself untiringly to its welfare and growth.

Always energetic in his efforts to uphold principle and justice, his loss will be felt in both County and State Society.

JOSEPH WILLIAM JAMES

1876-1924

On Saturday, December 13, 1924, Doctor J. W. James was borne reverently to the grave by members of the profession, by whom he was so highly esteemed and for whose welfare he so valiantly labored.

The twenty years and more of his career as a physician and surgeon were terminated at the height of his usefulness and endeavor, but if estimates of a life are to be measured, not by the number of years lived, but by the amount of good accomplished, then Doctor James furnished an example which few can equal, none surpass. If one is required to give an epitaph adapted to his character and career, "I live to serve" would be most fitting. To him, medicine was truly an art as well as a profession, and his happy buoyant nature, coupled with an unusual sense of duty, enabled him to bring hope and cheer when physical means failed.

Born of sturdy Welsh-English parentage, he came to this country early in life and literally carved his own career. Circumstances compelled him to rely chiefly on himself for support in his education, but his will to succeed readily overcame all obstacles and brought out that determination of character, which, knowing the right,

fight to achieve and always wins. Of the great numbers who employed him, there were none but remained his friends, for it was easy to realize that he gave himself wholly and freely to his tasks, no matter how trivial.

That which was finest and best in life guided his every instinct and act, as the loadstone and the star. Art, music, literature and things refining and cultural, always engaged his interest and support. His abundant enthusiasm and energy carried him far and, in good measure, were contagious. Without his support, the splendid Sutter Hospital, recently erected and operating, could hardly have been carried through. In spite of the demands of a large and exacting practice, he saw the new institution

functioning chiefly through his own efforts. His name is indelibly linked with it.

As a citizen, Doctor James more than performed his part: serving faithfully and for many years on the local Board of Health and the State Board of Examiners; in civic matters, he gave freely of his purse and time; all movements seeking better hygiene, social or economic improvements, had his enthusiastic support and undivided attention.

Though he persistently sought to enlist in the late war, impairments caused the authorities to restrict or decline his services. All honor to those who exposed themselves in the front line, but the war could not have been won without the united support of those "behind the lines," and of these Doctor James led in examples of patriotism and successful endeavor.

Life has been likened to a beautiful mosaic, built up of a number of small stones or bits, each one representing a deed well done. The good deeds accomplished by Doctor James have aided, bit by bit, in making of his career the picture of a good life, long to be cherished and revered by his friends and associates. Wise counselor and esteemed friend, he "sought to prove all things and to hold that which was good."

S. E. SIMMONS, M. D.

ALAMEDA COUNTY

Alameda County Medical Association (reported by Pauline S. Nusbaumer, secretary)—The program at the regular meeting of the Alameda County Medical Association held November 17 was devoted to a symposium on encephalitis lethargica. In his paper, "Epidemic Encephalitis from the Experimental Standpoint," William Lee Bender of San Francisco stated that recent investigations have established the presence of widespread spontaneous encephalitis in rabbits, throwing open to doubt results of previous experiments on the etiology of encephalitis in man. He and his co-workers have been able to immunize rabbits against experimental encephalitis, which offers a means of studying the relation of various strains of virus to each other. He further stated that no uniformly satisfactory treatment of epidemic encephalitis had been developed, that there is no specific therapy, and that it might prove possible to confer immunity to a man as well as to rabbits.

Albert H. Rowe, in his paper, "Clinical Aspects of Lethargic Encephalitis," went into the symptoms and physical findings in detail. The importance of following up cases of encephalitis was emphasized, since sequelae are apt to be accompanied by persistent mental irritation, insomnia, hallucination and, at times, neuritic pains in various parts of the body. In view of the severe sequelae and the progressiveness of the disease in such cases, any reports of successful treatment should be followed up. At this time protein injections, especially in the form of typhoid protein administered under the most careful supervision, seems to be of value. Reports of success with other forms of protein therapy, such as non-specific serum or milk injections, must be kept in mind.

Sydney K. Smith's paper, "Psychiatric Sequelae of Encephalitis Lethargica," included the consideration of the following points: 1. "Lethargic" encephalitis is a misnomer. 2. Encephalitis is a syndrome and not a disease entity. 3. The psychiatric sequelae may include behavior and character changes—adult and juvenile, manic or depressive episodes, emotional apathy and less often trend reactions. 4. Our knowledge of encephalitis is so recent that the ultimate psychiatric prognosis cannot properly be given. 5. Summary of series of seventeen cases.

The discussion of these papers was opened by R. T. Legge.

At the Fabiola Hospital staff meeting, R. L. Richards read a paper on "What We Think With," setting forth the development of the brain according to the different stages of growth.

A. H. Rowe gave a talk on the "Treatment of Asthma," disclosing new discoveries and noting the progress that has been made during the last four or five years.

Upon the retirement of Susan J. Fenton from the Fabiola staff, W. L. Bell said in part: "It is not necessary to say how faithful, honorable, and ethical Dr. Fenton has been during the long years of her service. She has given most generously of her time, her knowledge and her money. This fine gentle woman has been an honor to her profession and to this staff."

At the meeting of the Merrit Hospital staff on December 8, W. H. Barnes reported three fatal cases of infections with pyogenic staphylococci. Emphasis was placed on the importance of early recognition of the infection, absolute rest of patient and the infected part, proper elimination, and intelligent surgical intervention. Intravenous injections of gentian violet and mercurochrome failed to stop the advance of the infection in these cases.

A. C. Siefert spoke of his attendance at the annual meeting of the American Roentgen Ray Society at Swampscott, Mass., and his visits to the leading hospitals, both in the United States and Canada. The doctor saw much of interest, and found that each group of men had some special work in which they particularly excelled.

FRESNO COUNTY

Fresno County Medical Society (reported by T. Floyd Bell, secretary)—A special meeting of the Fresno County Medical Society was held at the Hotel Fresno at luncheon on November 15.

Those present were: Aller, Bell, Couey, Cowan, Cross, Ellsworth, Goldberg, Jamgotchian, James, Kjaerbye, G. L. Long, Luckie, Madden, Manson, Mathewson, Miller,

Montgomery, Morgan, McPheeters, Pettis, Schottstaedt, Sciaroni, Staniford, Stein, Thompson, Tillman, Tobin, Tupper, Vanderburg, Wahrhaftig, J. R. Walker, G. W. Walker, and Willson.

Gavin J. Telfer, district health officer of the California State Board of Health, discussed plague. He went into the history of plague in the old world, and also in California, and said that the disease was endemic among animals all over California. The first case was discovered in this state in 1900, and there have been several outbreaks since. The squirrels in the region of San Francisco harbor the infection and transmit it to humans. In July, 1924, it was noted that the rats and squirrels in the region of San Luis Obispo were dying rapidly, and investigation showed that 20 per cent were infected with bacillus pestis. More recently there has developed an outbreak in Los Angeles, with the pneumonic form prevailing. He spoke briefly of the symptoms of both the pneumonic and bubonic types. The mortality is very high, being 90 per cent to 100 per cent, with the pneumonic form. Those who do recover do so after about ten days, but the convalescence is long and drawn out. The organism is easily stained and cultures are definite. Animal inoculation is the positive test.

Prevention of plague is the important means of attack on the disease. Attendants must be protected by mask and goggles, as well as the other ordinary means of protection. Vaccination and serum has no relation to the control of the disease. The main means of prevention is eradication of the rodents. The measures that should be used in Fresno are those used to eradicate the rodents. There should be no squirrels within ten miles of the city and a minimum of rats in the city. Make the city as rat-proof as possible; sanitary inspection and rat-killing by experienced men.

Cross moved, Luckie seconded, that the secretary be instructed to secure literature on plague for the library. Carried.

The regular meeting of the Fresno County Medical Society was held December 2 at the Hotel Fresno with dinner, this being a social meeting.

Members: Aller, Anderson, Barret, Bell, Broemser, Collins, Cross, Craycroft, Callaway, Dearborn, Goldberg, James, Jorgensen, Kjaerbye, Konigmacher, Lamkin, Luckie, Madden, Manson, Mathewson, Miller, Montgomery, Mitchell, Morgan, Milholland, Pasley, Pettis, Pomeroy, Quimby, Schottstaedt, Sciaroni, Tillman, Tobin, Tupper, G. W. Walker, and Wilson.

Visitors: Dahlgren, Nider, Dow, and Mr. Ben Harrell.

Before being seated, Madden gave the following reading, in memory of the late A. B. McConnell.

"The shadows deepen and we set our faces toward the new year which time will soon usher in.

"The fading of the present year recalls to our minds the brother who answered the silent roll-call, and we pause.

"Let us turn to memory's storehouse and draw therefrom those fine fragments of recollection, the mere thought of which will supplant sorrow with joy.

"Let this be the occasion of a careful inventory of the past of the living, as well as a resumé of achievements of our dead in his earthly struggles, remembering always that the most endearing memorial we can erect will be a constant effort on our part to perpetuate by our faithful devotion to the principals of our profession those things that were dear to our departed brother.

"May he rest in peace."

The application for membership of O. P. Pisor of Monmouth was read.

The following officers were elected for next year: President, A. E. Anderson; first vice-president, W. G. Milholland; second vice-president, Charles A. James; secretary, T. Floyd Bell; assistant secretary, J. A. Montgomery; delegates, T. F. Madden, H. J. Craycroft; alternates, B. Lamkin, R. B. Tupper; board of governors, W. P. Miller.

Doctor Konigmacher had arranged a very pleasing and entertaining musical program, which was presented.

W. W. Cross gave an illustrated lantern lecture on the "Sierra Nevada Mountains." He was raised in the shadow of these mountains and has spent a great deal of time studying them and enjoying their wonders. He told how mountains in general were formed and how the Sierras came into existence and how the ocean washed

their western shores. He then showed pictures of many interesting and beautiful places in this rugged range of mountains.

KERN COUNTY

Kern County Medical Society (reported by William H. Moore, secretary)—The regular meeting of the Kern County Medical Society was held at the Kern County General Hospital November 20, 1924, P. J. Cuneo presiding. Twelve members of the society were present.

L. W. Blake, a new physician in Bakersfield, was present, and R. M. Jones' transfer of membership from Fresno to the Kern County Medical Society was accepted.

Clain F. Gelston of San Francisco read a paper on "Bronchiectasis in Children."

MERCED COUNTY

Merced County Medical Society (reported by Brett Davis, secretary)—The meeting held November 7 was without program, as Dr. Samuel W. Hurwitz, who was scheduled to appear, was unable on account of sickness to be present. December 4, the regular December meeting was held at Merced. Dr. Lee S. Seward of Ahwahnee T. B. Sanitarium and Dr. Charles L. Ianne of Arroyo Grande Sanitarium were present as visitors. These two doctors held a chest clinic the following day in Merced.

Election of officers for 1925 resulted as follows: President, A. S. Parker, Merced; vice-president, T. R. Trick, Dos Palos; secretary-treasurer, Brett Davis, Merced; delegate, W. C. Cotton, Atwater; alternate, C. H. Church, Yosemite.

C. F. Harrar, M.D., who has been in Merced for the past year, has just moved to Turlock, Calif.

While there has been no smallpox in Merced County, public clinics were held by the State Board of Health and county health officer, with about five thousand vaccinations.

ORANGE COUNTY

Orange County Medical Association (reported by D. R. Ball, secretary)—A very excellent paper was provided for the December meeting by Dr. F. E. Coulter of Santa Ana on "Observations on Functional Nervous Disease." The conditions of neurasthenia, psychasthenia, and hysteria were gone into particularly after a broad survey of the field had been given. A plea was made for the proper recognition and treatment of these conditions by the general practitioner.

Officers for the coming year were elected as follows: President, H. D. Newkirk; vice-president, Bessie S. Martell; secretary-treasurer, D. R. Ball; librarian, C. D. Ball; delegate, Harry E. Zaiser; alternate, R. A. Cushman; councillors, John Wehrly, F. E. Coulter, and G. M. Tralle.

The Santa Ana Clinical Society held its regular meeting at the office of the president, John Wehrly, on November 19. A. E. Belt of Los Angeles presented a very interesting lantern slide demonstration of "The Anatomy of the Kidney." The slides illustrated the work which the author did in conjunction with Frank Hinman of San Francisco in winning the gold medal awarded by the A. M. A. in 1921 for the best piece of scientific research of the year. Following this demonstration, Dr. Belt showed an interesting collection of x-ray pictures of various urological conditions.

The profession has, within the last month, lost two of its oldest members in the county. Dr. Willella Howe Waffle, age 70, of Santa Ana died on November 12 while attending a patient. She had practiced in this community since her graduation in 1886. She followed the Homeopathic school of practice. Dr. John L. Dryer, age 79, of Santa Ana died on November 30, after a two weeks' illness. He had practiced in the state since 1877, and in Santa Ana since 1888. He was a charter member of the Orange County Medical Association, and maintained his active membership until his death. Although in poor health for the last few years of his life, he kept up his work in his chosen field of tuberculosis until the last. The profession and the community have indeed lost two worthy and respected members.

Two new names have been added to the membership

list: George A. Paige of Anaheim was elected at the October meeting; W. A. Kisting of Santa Ana, transferring from Livingston County, Ill., was elected at the December meeting.

PLACER COUNTY

Placer County Medical Society (reported by Robert A. Peers, secretary)—The society held its annual meeting in Auburn, Saturday evening, December 6. This being the regular meeting for the election of officers, no literary program was presented.

The following officers and delegates were elected to serve for 1925: President, H. N. Miner, Blue Canyon; vice-president, J. A. Russell, Auburn; secretary-treasurer, Robert A. Peers, Colfax; associate secretary, Charles J. Durand, Colfax; delegate to State Society, F. E. McCullough, Lincoln; alternate, H. M. Kanner, Colfax.

It was decided to have the next literary program in Auburn late in January or early in February.

RIVERSIDE COUNTY

Riverside County Medical Society (reported by T. A. Carl, secretary)—At the annual meeting of the Riverside County Medical Society, officers for the year 1925 were elected as follows: C. R. Geith, president; W. B. Wells, vice-president; T. A. Card, secretary-treasurer.

SACRAMENTO COUNTY

Sacramento Society for Medical Improvement (reported by G. J. Hall, secretary)—At the November meeting forty-four members were present.

Presentation of Cases—Brendel reported a case of rupture of biceps tendon repaired; dislocated semi-lunar cartilage; lengthened quadriceps tendon. O'Brien reported a case of rupture of uterus at six months' pregnancy.

William J. Kerr of San Francisco discussed "Modern Methods of Treatment of Heart Disease." The essayist stated that the most important thing in treatment of cardiac disease is treatment of congestive cardiac failure—muscle failure—signs and symptoms. The principles of treatment are:

Rest most important in treatment of cardiac insufficiency—bed position. Diet: Easily digestible; no effort in mastication; no large amount; frequent feedings, concentrated food. Sleep is necessary—maybe morphine in certain types.

Depletion—Removal of fluid; may use magnesium sulphate; purgation; diuretics. Removal of fluids from body cavities; cupping; venesection 500 to 750 cc. of blood. Bandages in oedema of legs.

Stimulation—First, digitalis; second, caffeine. Diet: avoid gas-forming foods, large amounts of bread, etc. Mode of life to lead afterward. Right kind of work. Graded exercises to develop proper hypertrophy of heart. Prophylactic treatment, removing foci of infections. Digitalis most valuable—sometimes abused—no special indication in rapid heart. Heart failure; then digitalis. Many books state ten drops of digitalis is proper dose—variation in droppers and in tinctures themselves—use graduated dropper or graduate, or place in vehicle. Fifty drops from dropper equals 1 cc. in graduate. Superior to the use of dried or in pill forms. Few contra-indications for digitalis. Quinidine: Chief value in auricular fibrillation is to restore normal rhythm. If muscle failure with edema and anasarea, then digitalis first; later quinidine. May give six grains t. i. d. for three or four days, if first three grain doses are okay. If embolism or heart muscle extensively damaged, then quinidine is no use. Camphorated oil of no great value. Strychnine, long continued use as stimulant in vasomotor system. Whisky aromatic ammonia temporary.

Bacterial rheumatic endocarditis demands attention. Prognosis bad in 100 per cent. Usually young people with rheumatism; no results with any treatment. Saw none recover. Moffitt saw one recover.

For pulmonary edema: Prop up in bed; morphine and adrenalin. If blood pressure is high and cyanotic, should be bled. Take one pint or two pints. Long rest. Angina pectoris and coronary disease: Nitrates or nitroglycerin and rest; if syphilitic, iodides and arsphenamine. More

recently, operations on sympathetic nerves. Pain relieved. Danger of patient overdoing later because the pain is relieved. Luetic aortitis: Differentiate between patients with aneurysm and without aneurysm; if with aneurysm, do not give arsphenamine; if without aneurysm, give tremendous doses of iodides. Patients may die from arsenical treatment. Hypertension: We have probably gone a little too far in trying to reduce blood pressure to certain levels. Heart block: Atropine. Heart in pregnancy: Very few conditions demand intervention. Very few cases of heart disease that contra-indicate necessary surgical operation.

Discussion by Grazier, Gundrum, Reardan, Scatena, O'Brien, Twitchell, Brendel, Drysdale. Closed by Kerr.

Parkinson talked on the new directory of the C. M. A.

✱

SAN BERNARDINO COUNTY

San Bernardino County Medical Society (reported by E. J. Eytinge, secretary)—A meeting was held December 2 at the San Bernardino County Hospital. Fifty members present, thirty-five absent; fifty guests.

The program: "Allergy," by George Piness, Los Angeles.

The talk was illustrated and accompanied by practical demonstrations, both human and animal.

The following men have been elected to membership: H. Garcelon, Victorville; H. A. Bogue, Ontario; A. S. Garnett, San Bernardino; E. H. Hull, San Bernardino; O. H. Von Emon, San Bernardino; J. A. Patterson, San Bernardino; C. G. Newbecker, Rialto.

✱

SAN FRANCISCO COUNTY

Franklin Hospital Staff Meeting (reported by Ewald H. Angerman, secretary)—The monthly staff meeting of the Franklin Hospital was held on Monday, November 24, Dr. J. Wilson Shiels presiding.

The paper of the evening was "The Treatment of Asthma," by Samuel H. Hurwitz, M.D. This interesting topic was exceedingly well presented by Dr. Hurwitz, and discussed by J. Wilson Shiels and C. E. Taylor.

St. Joseph's Hospital Staff Considers Head Fractures—"The Treatment of Head Injuries" was discussed by Howard Naffziger before St. Joseph's Hospital staff of San Francisco on December 10, Dr. A. S. Musante presiding. Charts and sectioned skulls were used to illustrate the discourse. Treatment of depressed fractures and penetrating wounds from picks and axes is uniformly that of relieving the depressed skull and in opening up, cleaning and draining. Operations during shock should be avoided, as life-saving measures can seldom be withstood. After reaction, x-ray pictures and operation with local anesthesia are in order. Fissured fractures need no operation usually. If the base is fissured, we may have bleeding into the nose, ear or mouth. Meningitis supervenes in about 6 per cent of these, as well as all other compound fractures. Dorsal decubitus and ice cap are recommended.

The brain injury needs attention. Intracranial pressure is important. Acute intracranial pressure generally produces slow pulse, which, when below 50, is hazardous. Rise of blood pressure is overstated, being often due to precedent trouble (kidneys, heart, etc.). Pulse pressure is of concern; if high is dangerous and rises as the pulse rate falls, being often higher than the count and constituting an alarming symptom. Increasing stupor, alternations in respirations (stertrous or Cheyne-Stoke's), and rhythmic alternating restlessness (rarely mentioned in texts) are bad prognostic signs. High spinal fluid pressure is also a symptom. The best factor in determining the gravity is the way signs are going, rather than what they are at any one time. In the first four hours, one cannot usually form a sound judgment, and any radical treatment may be meddlesome. On account of shock the patient's chances are usually reduced rather than improved by operation so early. The percentage of all fissured fracture cases requiring operation is about 10 to 15 per cent, not including depressed and penetrating fractures. If there are signs of increasing intracranial pressure and hemiplegia or other focal signs, operation is demanded. Free fluid can be removed by decompression and

damage, but not true edema. Free fluid may be either blood or cerebrospinal fluid. Middle meningeal hemorrhage causes slowly increasing stupor and paralysis, but is often difficult to diagnose. May have classical signs and no hemorrhage, and vice versa. Intracranial bleeding from other sources often resembles it. Subdural fluid accumulations can cause high intracranial pressure and can be relieved. Spinal puncture two to three times a day can be used to relieve pressure. If pressure and fluid return promptly after the puncture, it is a case of subdural accumulation. Hypertonic solution, as 40 cc. of a 25 per cent salt solution, injected intravenously in about twenty minutes, can be used. The maximum effect will occur for two to three hours. Do not use in manifest kidney insufficiency. Salt by mouth and epsom-salt purging is used to dehydrate, but the effect is only temporary. Salts can be given by rectum. If the pressure is high enough, do a subtemporal decompression, over the temporal bone, and also explore base and motor areas, draining for twenty-four hours.

C. E. Nixon advised small doses of morphine and spinal puncture to quiet. Prognosis generally good, if patient survives first twenty-four hours except for meningitis. Late post-traumatic neurotic symptoms show up after several weeks or months. Roy Parkinson discussed eye and ear symptoms and the slight demonstration often seen in fatal cases. Dr. David Stafford stressed the advantage of local anesthesia. H. A. Deering quoted a case with possible late cerebral lesions, and A. S. Musante presented cases of terrific impact without fracture and unilateral congenital markings in x-ray pictures, resembling fracture line. L. B. Crow closed by exhibiting illuminated "Radiograms of the Cranium," many of which were taken with a new technique by the use of a 1/10 second exposure, and advised against rushing these patients while in shock.

Case histories were discussed by R. F. Grant (perforated gastric ulcer) and Arthur Sonnenberg (pneumonia with hemiplegia). Stafford spoke favorably of the service offered by the Community Chest to hospital obstetrical patients during their first week at home. C. E. French recommended the hospital "bond" or insurance policy issued to cover hospital expenses of the insured.

Officers elected for 1925 were A. S. Musante, president; F. A. Lowe, vice-president; L. J. Overstreet, secretary; and F. C. Keck, treasurer.

The program for January 14 will include: "Indications and Contra-indications for Tonsillectomy," E. C. Fleischer; "The New Dietitian's Work at St. Joseph's," Sister M. Dionysia.

On January 22, the patronesses of St. Joseph's Hospital, Mrs. W. T. Cummins, president, will give a soiree to the student and graduate nurses at the Y. M. I. hall, and the doctors of the staff are invited.

Southern Pacific General Hospital Clinical Meeting (reported by W. T. Cummins, secretary)—The regular monthly clinical meeting was held at the Southern Pacific General Hospital, Huntington hall, on Wednesday, December 3. There were about sixty physicians present.

Scientific Program—Symposium on Heart Disease: J. Wilson Shiels, "The Old, the Young; The Ideal Attitude Towards Cardiology." He reviewed the history of cardiology and generalized on the physician's viewpoint towards the various phases of cardiac pathology, and emphasized the importance of graphic methods of study; A. W. Hewlett, "Attacks of Arrhythmia," covering the different phases of the subject, with their significance, frequency and termination, together with the value of electro-cardiographic examinations; E. S. Kilgore, "Bacterial Endocarditis," including the salient points of the bacterial and sub-bacterial stages of the infection and noting the difficulties in some cases attending the bacteriological study of the early stage; W. J. Kerr, "The Treatment of Heart Disease," with a comprehensive review of the entire subject, including the use of quinine and its derivatives selectively in some instances by intravenous injection; M. P. Burnham, "Roentgen Demonstration," comprising a number of chest plates, one of which illustrated the importance of detection of an enlarged thymus. The aorta, as well as the heart, was reviewed.

Worthwhile Work for Department of Anthropology—Doctor Saxton Pope has recently returned from an extended vacation in the mountains of Tehama, Butte, and Shasta Counties. He undertook to explore and place upon

the map the various camp sites, battlegrounds and caves of the Yana Indians, and has made a valuable contribution to the knowledge of this extinct tribe. The work was done under the auspices of the Department of Anthropology at Berkeley.

Dr. Pope is spending his sabbatical year in research work of this sort, after twenty-five years of medical practice, and intends completing his vacation with a hunting trip into British East Africa, after which he will return to the peaceful pursuits of professional life.

Successor to Doctor Rethers Appointed—Doctor Tillton E. Tillman has been appointed a member of the San Francisco County Lunacy Commission to fill the vacancy caused by the death of Doctor Theodore Rethers. The other members of the Commission are B. J. McElroy, Arthur Beardslee, and Charles McGettigan.

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by Alex C. Soper Jr., secretary)—The regular meeting was held December 8, at the Cottage Hospital, Santa Barbara, President Robinson in the chair. Present, twenty-two members, one intern, and two guests.

Moved, seconded, and passed that a letter be written to the editor of the Scientific American, thanking him for the work in exposing the Abrams' machine, in the name of the society.

The membership of Joseph D. Lewis, by transfer from the Minnesota Medical Society, was unanimously voted.

The matter of a doctor's telephone exchange and operator, in connection with the Nurses' Directory, was outlined by Miss Jameson, superintendent of the Nurses' Association, by Drs. Robinson, Isaac, and Mellinger, in view of a plan to have a central point where calls for physicians could be sent in emergencies. Matter referred to Drs. Lamb and Isaac for further investigation.

Five-minute case reports followed: Partial Heart Block, H. O. Koefod; Obstruction of Bowel Following Appendicitis, H. L. Schurmeier; Traumatic Rupture of Membranous Urethra, Irving Wills; The Audio Amplifier, shown by W. J. Mellinger.

Egerton Crispin of Los Angeles delivered the principal paper of the meeting—"Angina Pectoris, a Measure of Exhaustion," which was discussed by Sansum, Nuzum, Pierce, Koefod, and Means.

SISKIYOU COUNTY

Siskiyou County Medical Society (reported by C. C. Dickinson, secretary)—At the fourth quarterly meeting of the Siskiyou County Medical Society, held in Yreka, November 3, the following officers for the ensuing year were elected: President, Dr. R. H. Heaney, Yreka, Calif.; vice-president, Dr. W. H. Haines, Etna Mills, Calif.; secretary-treasurer, Dr. C. W. Ankele, Dunsmuir, Calif.

At the same meeting the application for membership in the society of David Joseph Mahan, Fort Jones, Calif., was accepted, subject to confirmation by the A. M. A. and State Board of Medical Examiners.

SONOMA COUNTY

Sonoma County Medical Society (reported by N. R. H. Juell, secretary)—The society met at Santa Rosa December 11, with seventeen members present, twenty-three absent, and two visitors.

There was no definite program; only election of officers and a social gathering.

The officers elected were: President, A. M. Thomson, Sonoma; vice-president, G. W. Mallory, Santa Rosa; secretary, Guy A. Hunt, Santa Rosa; treasurer, R. M. Bonar. Censors: (three years) S. Z. Peoples, Petaluma; (two years) E. Emerson, Santa Rosa; (one year) J. H. McLeod, Santa Rosa. Delegate, A. A. Thurlow. Alternate, M. J. Fulmer.

CHANGES IN MEMBERSHIP

New Members—Ben. F. Eager, John C. Dement, San Diego; Gerald H. Beck, George C. Brandt, R. M. Hippach, Thomas P. Manning, E. Stafford Safarik, Albert J. Scholl, Ernest W. Townsend, Los Angeles; W. Arden

Fate, Santa Monica; Wallace W. Holley, Inglewood; Lawrence L. Lindsey, Hermosa; W. F. Kistingner, Santa Ana; George A. Paige, Anaheim; W. S. Wallace, Orange; Gordon E. Hein, San Francisco.

Transferred—Samuel Hanson, San Francisco County, to Alameda County; Clement H. Arnold, San Francisco County, to Santa Clara County; Robert M. Jones, Fresno County, to Kern County.

Resigned—W. D. Clark, San Francisco.

Retired—Louis Bazet, San Francisco.

Honorary Member—T. W. Huntington, San Francisco.

Reinstated—Giles S. Porter, Los Angeles.

License Revoked—Olaf A. Kvello, Los Angeles.

Deaths—Beckman, Oswald Heribert. Died at Glendale, November 28, 1924. Graduate of Jefferson Medical College, Pennsylvania, 1884. Licensed in California in 1895. He was formerly a member of the Mendocino County Medical Society, the California Medical Association, and the American Medical Association.

Dryer, John L. Died at Santa Ana, December 1, 1924, age 79. Graduate of the Cincinnati College of Medicine and Surgery, Ohio, 1877. He was a member of the Orange County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Hendricks, Hiram Porter. Died at Pasadena, September 28, 1924, age 50. Graduate of Northwestern University Medical School, Chicago, Ill., 1908. He was formerly a member of the San Diego County Medical Society, the California Medical Association, and the American Medical Association.

James, Joseph William. Died December 11, 1924, at Sacramento, age 49. Graduate of Cooper Medical College, San Francisco, 1900, and licensed in California the same year. He was a member of the Sacramento County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Rethers, Theodore. Died at San Francisco, November 21, 1924, age 57. Graduate of the University of Berlin, Germany, 1891. Licensed in California in 1892. He was a member of the San Francisco County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Van Tine, Cothran. Died at Selby, October 27, 1924, age 67. Graduate of Pulte Medical College, Cincinnati, 1890. Licensed in California in 1914. He was a member of the Santa Cruz County Medical Association, the California Medical Association, and a Fellow of the American Medical Association.

STIMULANTS, DEPRESSANTS, HUMOR

In reading the article in the A. M. A. Bulletin entitled "What is Wrong with the County Society" (see page 69 of this issue of C. and W. M.). That is what has been troubling me for ten years past. The — County Medical Society during this time has been a dead letter. I, a member, have not had notice of a meeting being held for about three years, and for approximately that length of time there has been no regular election of officers. The medical men of this town are divided into groups or cliques, who are antagonistic to each other to such a degree that I doubt if any argument could get them to work in harmony. If other counties of small membership are in the same predicament—that's what's the matter with the County Society.—R. C., —.

The Medical "Mossback," God Bless Him!

My first bit toward the education of the Mossback (old-time family physician) was done on my father," writes Roland G. Breuer (Journal of Kansas Medical Society). "It was almost my first call case—a boy of 16, with a regular afternoon temperature, higher each day, toxicity—all of the symptoms of a typical Oslerian typhoid. Promising the parents a discouraging session of six to eight weeks, I succeeded in impressing them with the gravity of the case. I permitted my father to accompany a real medical man and watch him work. With due humility he followed me, and humbly asked permission to make a cursory examination, a request which I magnanimously granted, explaining to him, the while, that in several days the Widal test would become positive—a thing which he indelicately refused to believe. However, after I gave him a good lecture, he subsided. On the following day he volunteered to stop and see the case on his way to the

offlee. With misgivings I gave my consent. Late that afternoon I hurried over for a specimen of blood for another Widal. The boy was sitting up; there was a sparkle in his eye, snap to his smile and a sting to his grin. A large wad of dressing was in his left axilla—my benighted father, refusing to wait for a Widal, had found an axillary abscess, lanced it, drained it, and shot a durned good diagnosis of typhoid fever all to thunder."

I have been very much interested in your editorials and consider them the best published in any medical journal, as they cover live topics, subjects that concern the doctor's future welfare, but which policy causes most medical leaders to straddle, and then a few years later when the damage has been done they make their cry. I subscribe for seven medical journals and I honestly believe that California and Western Medicine is not only the most attractive but the most valuable that comes to my desk.—M. B. W., San Francisco.

Father—Tommy, stop pulling that cat's tail.

Tommy—I'm only holding the tail; the cat's pulling it.

When all is said, the general practitioner, the real trunk of our tree, is the man who can do most at solving the problem of feeding infants.—E. M. T., Los Angeles.

Thank you very much for your recent letter and for your helpful criticisms of my paper on—. The paper was much better for the purposes of delivery at the County Society, than it was for publication in its present form. With your kindly and valuable suggestions in mind, I shall divide the paper into two parts and make certain revisions. I realize that I have demanded far more of your time than was right, in connection with a communication, which at first sight showed its unavailability for publication in California and Western Medicine. I am fully appreciative of your kindness and I wish you to know that I have a very high regard for your judgment in the matter at hand. May I take this opportunity to tell you of ever-increasing satisfaction being felt by medical men with whom I come in contact, for our State Journal? Your untiring efforts are surely bearing fruit.—J. C., San Francisco.

Have no additions or corrections to make on my paper. I think your plan of discussion is excellent and greatly adds to the value of the paper.—W. M. H., Los Angeles.

Some time ago the editor returned a manuscript of mine, saying that if I would reduce its size he would be glad to publish it. Since that time, however, you have published an article of mine. So with your permission I will not re-submit this article, since it seems to me that it would be rather selfish on my part to ask publication of two articles in one year.—H. K. B., Los Angeles.

Dentist—So you have broken off a tooth, have you?

Patient (tough youngster)—Yes, sir.

Dentist—How did you do it?

Youngster—Oh, shifting gears on a lollipop!

I am sorry to say that I have been ill and away from my office for some ten days, returning yesterday. For that reason I am late in returning the paper at the time indicated in your letter. I trust it will not inconvenience you too greatly. I am very much interested in these papers and I hope you will not hold this against me in the future when asking members to discuss papers.—A. L. D., Torrance, Calif.

Does the Child Always Resemble the Father?

Terence—"Tis a fine kid ye have here. A magnificent head and noble features. Could ye lend me a couple of dollars?"

Pat—I could not. 'Tis me wife's child by her first husband.

Popular Medical Lectures—The Stanford University Medical School announces the forty-third course of popular medical lectures, to be given at Lane Hall, north side of Sacramento street, near Webster, San Francisco, on alternate Friday evenings from January 9 to March 20, 1925. The dates, subjects and speakers are:

January 9—"Influenza and Common Colds," Dr. A. W. Hewlett.

January 23—"Migration as a Factor in Communicable Diseases," Dr. W. N. Dickie, Secretary of the State Board of Health.

February 6—"Parasitic Infections," Dr. N. E. Wayson, United States Public Health Service.

February 20—"Constipation and Auto-Intoxication," Dr. W. C. Alvarez.

March 6—"Loss of Life from Preventable Diseases," Dr. W. C. Hassler, Health Officer of San Francisco.

March 20—"Vaccines and Serums," Dr. E. W. Schultz.

The Poor Boy and Medical Education—"The medical profession must not by any circumstance of excessive costs of medical education allow its doors to be closed to the poor boy. Ways and means, endowment and gifts, must be provided for the fulfillment of his medical call," says the Cincinnati Journal of Medicine editorially.

California Board of Medical Examiners

(Reported by C. B. Pinkham, Secretary)

According to the San Francisco Herald of December 1, 1924, James William Richards, M. D., once a highly respected physician of Newark, N. J., pleaded guilty before Federal Judge John S. Partridge to a violation of the Harrison Narcotic law, and was sentenced to two years in Leavenworth prison. Dr. Richards was declared to have had a forged narcotic prescription at the time of his arrest. According to reports, on September 24, 1923, James William Richards, M. D., pleaded guilty to a narcotic charge in Los Angeles, and was sentenced to 180 days in the county jail. A citation has been served on Dr. Richards, returnable at the February, 1925, meeting, to show cause why his license to practice in the state of California should not be revoked.

Leon Hurwitz, licensed to practice in California some years ago, was recently sentenced to three years in Leavenworth penitentiary, on a charge of violation of the Harrison Narcotic Act and has been served with a citation, returnable at the February, 1925, meeting, to show cause why his license to practice in California should not be revoked.

J. C. Gancsu, posing as a doctor of medicine, was recently arrested in Pasadena on a charge of violation of the Medical Practice Act. According to newspaper reports, he had two concealed cameras in his office and thereby had taken the photographs of some one hundred patients in unconventional attitudes on his operating-table. Gancsu, while doing some electrical repair work, is reported to have taken the Ohio and California licenses of Drs. Ralph W. and Harriet C. Reynolds, having erased the name of Harriet Reynolds and written in the name of Joseph C. Gancsu; also, to have removed the Ohio seal. A reproduced copy of an Ohio license in blank was seized at the time of Gancsu's arrest; also, reproduction of the city of New York certificate of registration in blank, it evidently being Gancsu's intention to start a "diploma mill."

Francis Eugene Elmer, arrested in San Francisco, February 13, 1924, on a charge of violation of the Medical Practice Act, and who was held to answer May 21 for trial, left the jurisdiction of the court. Dr. Elmer is one of those indicted by the San Francisco Grand Jury in connection with the diploma mill frauds. He has been reported as "making himself obnoxious to the American colony" in Mexico City.

Charges against three Chinese herb doctors, recently arrested in San Francisco for violation of the Medical Practice Act, were dismissed by Police Judge Golden on November 28, 1924, on the ground of insufficient evidence.

W. L. Martin, claiming to be a graduate from the American University of Sanipractic, Seattle, Wash., arrested in Long Beach on a charge of violation of the Medical Practice Act, pleaded guilty on October 28, 1924, and was given a suspended sentence of sixty days in the county jail. A search of Martin's office disclosed, among other things, a speculum, four sounds, thirteen bottles of drugs or medicines, etc. Reports from Washington state that quo warranto proceedings to revoke the charter of the American University of Sanipractic have been instituted by the Attorney-General of the state of Washington.

Slapping Her on the Wrist—Complaint was made to CALIFORNIA AND WESTERN MEDICINE by a Visalia physician that a woman unlicensed to practice medicine was doing some dangerous things. Photographs were submitted, showing a most deplorable condition of a man's jaw, said to have been aggravated by her improper treatment.

The complaint and photographs were forwarded to the Board of Medical Examiners. Their special agent investigated and promptly arrested the woman. She was charged before a Fresno judge, pleaded guilty, and was given a suspended sentence for six months.

Correspondence

The July, 1924, number of CALIFORNIA AND WESTERN MEDICINE carried an editorial entitled "Fantastic Schemes for Formularizing and Socializing Medicine." Many messages commendatory of the editorial have been received, and one letter written on the stationery of the Public Health Center of Alameda County is as follows:

October 17, 1924.

Dr. W. E. Musgrave, Editor California and Western Medicine, Balboa Building, San Francisco, California.

My dear Doctor Musgrave—In a recent issue of California and Western Medicine (Vol. XXII, No. 7) there was an editorial headed "Fantastic Schemes for Formularizing and Socializing Medicine." The conclusions in the editorial were apparently drawn from extracts from an article, "Health Surveys in the Oakland Public Schools," in the Alameda County Public Health News (Vol. II, No. 3), as frequent quotations from this article are given. The article states, in italics, that "it is findings like these upon which parents rely to safeguard the health and lives of their children."

Knowing that it is the desire of California and Western Medicine to be entirely fair, the Board of Directors (Public Health Center), to whose attention the criticism was called, have instructed me to make a reply, knowing that your idea of fair play will be such that you will publish it.

The purpose of these health surveys seems to have been misunderstood and other parts of the article quoted overlooked. As stated in the article, "you will notice that at no time (as based upon this survey) has a diagnosis been made; merely the fact recorded that a defect is suspected." The survey is a series of simply objective tests recommended by leading specialists about the San Francisco Bay who had in mind the method in which they were to be used, and are intended to find the children that are apparently well, so that they may be eliminated from special attention.

"To verify the survey findings and to gain the co-operation of the parents in the promotion of their children's health, eleven community centers have been established. The doctor is in each of these centers one morning or afternoon a week." "With the parent or guardian of the child present, the physician makes a thorough examination." The children are seen by appointment only, and the physician himself regulates the number of appointments. Each doctor sees on an average from three to five children an hour "conferring (with the parent) as to the best way of improving the child's health. If there is a family physician or dentist, the child is referred to him by the school doctor on a form provided. If not, the parents are advised to select and consult one. Should they state they are unable to pay for medical service, they are referred to the medical social service department at the treatment clinic of the Public Health Center, a card being given stating time and place."

Yours very sincerely,
ALVIN POWELL, M. D.,
Director.

Comment—Yes, we don't.

Dear Doctor—I have just been reading the article on throat swabs in the enclosed bulletin (official bulletin, State Board of Health), and am mad.

We have enough slams from the lay health worker, etc., at present, without a member of our profession in an official position going out of his way to furnish them with ammunition.

Since when have laboratory technicians developed a system of ethics or a sense of responsibility?

Since when have the ethics and honor of the average M. D. been improved and purified by his acceptance of a

political job so that he may be trusted beyond the rank and file of our profession?

I have known a health officer to put a scarlet fever patient of his own in a back room, with the sign on the door of the room; nothing on the front of the house, and then allow the sister of the patient to give music lessons to children in the front rooms.

I have known of the assistant to a health officer to hand the swab to a 7-year-old boy and tell him to take the culture, etc., etc. (Signed) DOCTOR X—.

Note—The paragraph referred to by the writer reads:

"The importance of absolute exactness in diphtheria diagnosis, made possible by correct report of cultures from the throat and nose, makes obvious the necessity of a proper technique in taking swabbings for cultural tests for diphtheria. Even so simple a procedure is often inadequately or carelessly done with a resulting report which may mislead. *Laboratory technicians* sometimes wonder if poor swabbings are not sent intentionally to obtain negative findings. For release, it has been deemed safer to have the swab taken by the *health officer* or *his assistant*."

STATE BOARD MEDICAL EXAMINERS

Sacramento, Calif., November 6, 1924.

Re: Anesthesia.

Dear Dr. Musgrave—Our legal department has held that the giving of an anesthetic by a nurse constitutes a violation of the Medical Practice Act.

In the standardization of hospitals, does your committee make any point of this important feature; i. e., is it required that anesthetics in an approved hospital must be given by one licensed under the Medical Practice Act in the state of California?

Very truly yours,

C. B. PINKHAM, M. D.,
Secretary-Treasurer.

CALIFORNIA AND WESTERN MEDICINE

December 3, 1924.

Dear Doctor Pinkham—This is in reply to your letter inquiring whether or not we will accredit a hospital where anesthetics are given by other than licensed individuals.

In view of the fact that the Council on Medical Education and Hospitals of the American Medical Association, in consequence of your similar inquiry to them, has invited my comment upon the same point, it seems advisable to again answer this question rather fully.

We have not required that anesthetics be given only by an educated physician in our hospital betterment work, except in those hospitals purporting to teach anesthesiology.

Some years ago the House of Delegates of the California Medical Association passed unanimously a resolution recognizing the giving of an anesthetic as the practice of medicine and created an anesthesiology section in the California Medical Association. The opinion of the attorney of your Board of Medical Examiners, as well as an opinion of the Attorney-General, to the effect that the giving of an anesthetic by other than one licensed to practice the healing art constituted a violation of the laws of California was important evidence in influencing the California Medical Association to take the action it did.

Since that time, in hundreds of public addresses, letters, personal visits to hospitals, and repeatedly in CALIFORNIA AND WESTERN MEDICINE and in BETTER HEALTH, I have urged that, inasmuch as we have made anesthesiology the practice of medicine in principle, that we follow that principle to its logical conclusion in practice. This I have done as chairman of the Hospital Betterment Service of the League for the Conservation of Public Health, which committee, as you know, has by delegation of authority represented the California Medical Association and the Council on Medical Education and Hospitals of the American Medical Association for years in the hospital work in California.

With the co-operation of your board, the three Class A medical schools of the state and the members of the Section on Anesthesiology, the League was able to secure an

amendment to the California Medical Practice Act, requiring the teaching of anesthesiology to medical students. Much more has been done in a consistent, sustained effort to develop a wider appreciation of anesthesiology as a medical specialty.

However, as stated above, we have not as yet made it a *requirement* for accredited hospitals for many reasons, a few of which may be mentioned.

License—This, as you know, does not mean enough in California to warrant our using it as a basis from which to classify anything pertaining to health. There are persons whose state license probably grants them legal authority to give an anesthetic who would not be permitted to give an anesthetic or practice the healing art otherwise in any hospital accepted as an institutional member of the League or accredited by the American Medical Association. Then, too, the legal phase of the question has not been cleared up. The accuracy of the opinions of your attorney, that the giving of an anesthetic is the practice of the healing art, could be very readily tested in court and if sustained and law enforcement pushed, it would help clarify the problem. It has been, and still is easy to get evidence, and the Board of Medical Examiners is at least one of the boards charged with the enforcement of the law. If I mistake not, *there are government hospitals, as well as others, in the state where even unlicensed persons have been and are giving anesthetics.*

Other Legal Difficulties—The absence of court decisions in California and their varied trends elsewhere makes even a moral force—which is all we pretend to have—hesitate to get too far ahead of public opinion, particularly about a matter which is not of nearly the importance of other matters claiming our attention. Some superior courts have ruled that the surgeon is responsible for the anesthetist's work; others have ruled that the anesthetist is responsible whether licensed or not; others have ruled that the hospital is responsible, and there are still other slants deducible from court records.

What Constitutes an Anesthetic—There is much difference of opinion on this point. Some claim that a few whiffs of ether or gas during labor or in a dentist's office is not the giving of an anesthetic. Some would include these and the use of scopolamin and any and all of the various substances and methods used in producing local anesthesia.

Not Enough Educated Anesthetists Available—There are many places in this and other states where no educated doctor of medicine is willing to give an anesthetic except in emergencies and to selected patients. There are, of course, enough of specialists and young physicians who are willing to give anesthetics in the larger centers, but even here, as you know, many of the highly respected surgeons and obstetricians prefer their own specially trained technicians to give their anesthetics.

And so I might go on for pages telling of other facts to this many-faceted problem as it has presented itself to me in my hospital and other medical economics work.

These complications in the aggregate have induced me, and those I speak for, to limit our efforts to education and persuasion, hoping that, in the course of time, we will be able to make a *requirement* of what we now cover with a *request*.

If I have failed to make my answer clear, or if there is any assistance I can give you in what I assume is the beginning of a movement for law enforcement, please call upon me.

Sincerely yours,

W. E. MUSGRAVE,
Chairman Hospital Betterment Service.

Gurdon Potter, M.D., in a letter to the editor says:

"On page 647 of the December issue you quote a surgeon as having said, 'that anyone who believed in physiotherapy was the son of a quack.' I am sorry for this man, because just such an attitude in the profession has kept it in the narrow groove it has occupied for so many years, and allowed the birth of half-baked cults to arise on every hand.

"I have been a student of the application of 'mechanical means on a physiological basis' to the correction of pathology in the human body for the past twenty years, and have been given the laugh many times for my views in the matter. However, I have yet to see it fail, if your

diagnosis is correct, and you know your pathology. Richard Cabot well says 'that 50 per cent of our diagnosis is incorrect.' Physiotherapy is not a 'cure-all,' and never will be. Neither is anything else, but, brother medical man, there is some truth in physiotherapy, hydrotherapy, and other controllable agencies if you have an open mind to investigate them, and really investigate them, and not take the 'barbershop chatter' that so often passes as 'gospel' in some medical groups.

"No wonder that H. C. Wood said, thirty years ago, 'if further progress is to be made we must question the old methods and search out new, which may happily lead to more fruitful fields.' Yea, verily. At the present time the really big minds in bacteriology frankly say that we are again approaching a somewhat similar condition in that branch—or words to that effect. In the light of common sense, and for the sake of real progress—yes, for the love of Mike—wake up, get out of the rut, look things over, and if they don't prove up, scrap the whole thing—but stop, look, and listen."

Tryparsamide in the Treatment of Neurosyphilis—

Udo J. Wile and Lester M. Wieder, Ann Arbor, Mich. (Journal A. M. A., December 6, 1924), attempted to determine the value of tryparsamide in the treatment of neurosyphilis, as well as to determine the toxicity and the untoward reactions of the drug, if such existed. Fifty cases of cerebrospinal syphilis were utilized. In the neighborhood of 325 injections were given to these patients. The fifty cases allow of the following differential clinical analysis: General paralysis, twenty-one cases; taboparesis, six cases; tabes dorsalis, three cases, and diffuse cerebrospinal syphilis, twenty cases. Tryparsamide showed itself of great service in causing a profound change for clinical betterment in these cases. The type of case found most favorably influenced has been the type in which least might be expected, namely, the parenchymatous type in which a considerable degree of deterioration had apparently occurred. The most striking clinical changes noted have been increase in weight, color and general appearance. In nine cases, a marked improvement of the mental state of the patient has been found coincident with the improvement in the general appearance. In five cases, the treatment was followed by clinical improvement when other forms of therapy, including intraspinal treatment, had failed. This clinical betterment is not paralleled by striking corresponding changes for the better in the spinal fluid. For this reason, it is possible that the improvement characterized by gain in weight and general appearance may be due partly to the effect of the drug on syphilitic foci outside the nervous system, as well as to the tonic effect of the arsenic content of the drug. Gastric crises and the lightning pains of tabes dorsalis have, as yet, not yielded to tryparsamide treatment in this series. It would appear that more treatment of the same type should be given in those cases in which no laboratory response has been noted, on the one hand; and that a greater period of time must elapse, on the other hand, before accepting clinical improvement as definitely evident of the therapeutic activity of the drug. With the exception of vomiting, which followed each injection in one case, in no other case was there the slightest untoward result, either from the standpoint of constitutional reaction or from that of disturbance of vision.

Another Middleman in Medicine—In commenting editorially upon another great corporation planning to practice medicine wholesale, the Illinois Medical Journal says that they are going to establish a system of industrial surgery in New York City, with its beginning a series of first-aid stations placed at intervals throughout the city. This application of "chain-store methods" to the practice of medicine by a corporation of lay people will be as appalling as it is brazen, and is a direct attack upon the health welfare of the community.

"Fifteen per cent of all pregnancies result in miscarriages, and 5 per cent in stillbirths," says Charles Herriman, secretary New York Children's Welfare Association. Three times as many deaths occur in utero and at birth, as during the first year of life.

Utah State Medical Association

SOL G. KAHN, Salt Lake City.....President
 WILLIAM L. RICH, M. D., Salt Lake.....Secretary
 J. U. GIESY, 512 Felt Bldg., Salt Lake City,
 Associate Editor for Utah

HAPPY NEW YEAR

A new year! Always it seems to mean so much. Another twelve months, a whole wonderful chain of three hundred and sixty-five and a quarter days in which to live, and work, and serve. It is a wonderful, an exalting, uplifting thought. It fills the heart with hope. To all you men of the medical profession who follow the calling of helpful service in the great state of Utah, to all of our brothers elsewhere—A Happy New Year. We can wish you nothing better on earth.

DESERVED CONFIDENCE

Those of you who follow the daily news may have read the following, under date of Tuesday, December 2, 1924: "Five persons are charged with practicing medicine without obtaining a license." If not, read it further along in this month's notes. Here is at last a practical illustration of one of the chief functions of the State Board of Registration—an illustration of how it should work. We who practice under the law, should realize that we have a duty to the body politic beyond the mere prescribing for human ills. To relieve suffering, to halt the course of disease is a noble work; but to safeguard the man who is ill, whose life may be in danger, is as much the duty of the doctor as that of the guardian of the law who shoots a dangerous animal on the street. Times change. With the passing, in a measure, of the "family doctor"—he who was physician, friend, and advisor of his patients in the past—let us not forget that the average patient is a man or woman who needs advice—a friend as well as a physician—that he knows not as we know what is genuine, what is worthy of trust and confidence as applying to our craft. It is on this almost childlike confidence, this ignorance if you like, this unfortunate gullibility of the masses that the cults flourish and grow temporarily fat. Hence, it is to the doctor, after all, to see that the standards of the profession are maintained and raised. The doctor, through the legal channels of the state machinery and his own committees on health and legislation may serve his fellow-man and his fellow-craftsman thus. Let those who are not qualified be cast out, cut off. The unqualified physician is as dangerous to the unsuspecting dupe of his pretensions as a dangerous drug. "He who steals my purse," says Shakespeare, "steals trash. But he who steals my reputation—" And what of the man who through ignorance, false pretense, personal greed, loses a patient's life? He steals—all. More power to the committee on health and legislation in their endeavors to ferret out and bring under the law men of this sort. In so doing they are protecting the people of the state, conserving their interests and their lives. And in so doing—in beginning this new year in this fashion—let us hope that they may win, not only their own and

ours, but the entire commonwealth's confidence and respect. Service is the great keynote of true human association, and how can one serve better than by safeguarding and defending human life against the wiles of that type of harpy which battens off of human pain and sickness, as the other type of harpy was supposed to batten off of human flesh. Let medicine today draw a sword of righteous indignation and, literally, protect the innocent.

Utah Notes (reported by J. U. Giesy, associate editor)—Salt Lake County Hospital Clinic Meets—The clinic of the Salt Lake County Hospital met Friday evening, November 28, at the hospital. The following subjects were presented: "Typhoids and Effect of Typhoid Immunigen," George R. Roberts; "Bladder Tumor in Child Four Years of Age," discussed by W. W. Barber and W. C. Cheney, and "Interesting Spine Cases" by A. A. Kerr, F. D. Calogne and Foster Curtis.

Illegal Practice of Medicine Is Charged—Five persons are charged with practicing medicine without obtaining a license in complaints issued from the office of the county attorney. Those named are Vonner E. Raymond, Alma S. Ash, Albert T. Faerber, Harold Hulme, and Spyros J. Parthenon.

Community Clinic Ends Busy Year—At the annual meeting of the Community Clinic and Dispensary, reports were presented by Harold M. Stephens, president; Miss Eva Hollis, treasurer; Dr. George W. Middleton, managing trustee; and by Mrs. M. S. Avery, executive secretary.

Following the reports, a resolution of respect for the late A. N. McKay was passed, and also a resolution thanking the Salt Lake County Medical and Dental Societies, who furnish the entire clinic staff.

The following trustees were elected: W. W. Armstrong, Dr. A. J. Hosmer, H. N. Byrne, F. M. Critchlow, and Harold M. Stephens. Following the regular meeting of the clinic, the board of trustees met to elect the new officers for the coming year, who were elected as follows: President, Harold M. Stephens; vice-president, Amy Brown Lyman; secretary, W. N. Williams; treasurer, Mr. Fitzpatrick, to succeed Mr. McKay.

Reports given at the meeting showed that a total of 3184 patients had been treated during the year, of which 1118 had never before received treatment from the clinic, while 2066 were patients who were returning for additional treatment. The report on the character of the treatment given showed 833 medical cases, 572 surgical, 1459 eye, ear, nose and throat, and 320 dental; also, 74 radium treatments. The patients sent to hospitals numbered 253, four of these receiving major operations, and 249 receiving minor operations.

The Salt Lake Community Clinic and Dispensary was founded by a number of business men of Salt Lake, of which the late A. N. McKay was one, for the purpose of giving free medical attention to those unable to secure it for themselves.

A Family Doctor One Hundred Years Old—Friends Honor Pioneer Utah Physician—The Centennial anniversary of Dr. Harvey C. Hullinger was recently celebrated in Vernal, Utah. Dr. Hullinger was born fourteen years after Lincoln, and was 2 years of age when Thomas Jefferson died. He came to Utah from Iowa in 1859, and served in the Civil War as a physician.

The celebration was probably the largest birthday party in the history of his county. The honor guest was presented with a leather chair, as a gift from the community. The large building was packed to capacity and many pioneers were present, as well as young people.

Dr. Hullinger made a touching address, and throughout the day refused to allow anyone to assist him as he moved about. He would say, "Don't take hold of me, you might pull me down." Dr. Hullinger has living twenty-five grandchildren, eighty-one great-grandchildren, and twenty-four great-great-grandchildren.

Dr. Hullinger received the following message from President Coolidge: "Dr. Harvey C. Hullinger, Vernal, Utah: My congratulations to you on this remarkable anniversary occasion. You have my sincere wishes that you may celebrate many returns of the day."

He also received telegrams from Governor Charles R.

Mabey, Congressman Colton, President Heber J. Grant, and many others. He was escorted about town by Messrs. McGraw and McPherson of Salt Lake City, in a beautiful new automobile.

According to Special Order No. 171, Headquarters 104th Division, United States Army, dated December 6, 1924, paragraph 6, Major John U. Giesy, Med. O. R. C., Felt building, Salt Lake City, Utah, is relieved from the 413th Infantry and is assigned to Headquarters 329th Medical Regiment as Division Medical Inspector.

Salt Lake Society—Secretary Critchlow makes an interesting 1924 annual report that might well be studied by county medical societies everywhere:

Number of regular meetings held, 18, including this meeting; number of special meetings held, 1; number of meetings open to the public, none; number of meetings held at hospitals, 3; largest attendance at meetings, 104; smallest attendance at meetings, 41; average attendance at meetings, 60; largest attendance of visitors at meetings, 24; smallest attendance of visitors at meetings, 1; average attendance of visitors at meetings, 5; number of clinical cases shown other than at hospitals, 17; number of papers read by members, 28; number of papers scheduled and not read, 2; members on 1923 roll, 209; members left town in 1923, 2; members paid dues in December, 1923, 5; members admitted in 1924, 19; grand total for year, 231; members moved from town in 1924, 2; members died during 1924, 4; members suspended for non-payment of dues, 1; active members this date, including honorary members, 224.

Members Elected—Fifteen, as follows: Newton Miller, F. G. Eskleson, George E. McBride, E. R. Van Cott, J. Clinton Bown, Burtis F. Robbins, Scott A. Jones, Edwin R. Murphy, Sam G. Paul, William R. Cannon, F. K. Root, M. Skolfield, G. H. Pace, S. H. Besley, Charles W. Woodruff.

Members Elected by Transfer—Four, as follows: D. W. Henderson, Juel E. Trowbridge, R. O. Porter, G. Wallace Hanks.

Deaths—Death has taken a heavy toll from the society during the year 1924. L. B. Laker of Eureka, Utah, died February 7, 1924, following an operation. J. Lane of Salt Lake City died of pneumonia March 18, 1924. J. F. Critchlow, Salt Lake City, died in an automobile accident July 24, 1924. Ernest Van Cott of Salt Lake City died of angina pectoris August 27, 1924. Patrick S. Keogh, an ex-honorary member, died November 25, 1924, of uremia.

Officers—The following officers have served during 1924: President, A. A. Kerr; vice-president, John Z. Brown; secretary, M. M. Critchlow; treasurer, J. E. Jack.

Board of Censors—T. A. Flood, term expires 1924. E. D. Hammond to serve one year. F. A. Goeltz to serve two years.

Delegates Whose Term Expires in 1924—E. F. Root, E. D. Hammond, W. G. Schulte, F. F. Hatch, J. Z. Brown, J. P. Kerby, J. E. Tyree, F. A. Goeltz, T. A. Flood.

Holdover Delegates—A. A. Kerr, E. M. Neher, C. L. Shields, V. J. Clark, A. C. Behle, W. R. Tyndale, H. P. Kirtley, F. B. Steele, J. C. Landenberger, M. M. Critchlow, Ernest Van Cott (deceased), W. R. Calderwood, D. L. Barnard, etc.

Alternates—W. F. Beer, F. E. Straup, T. B. Beatty, Clifford Pearsall, David Smith.

Committees

Public Health and Legislation—Ernest Van Cott, chairman; R. R. Hampton, J. J. Galligan. When Ernest Van Cott died, Dr. R. R. Hampton was made chairman and Sol G. Kahn was appointed on the committee.

Library Committee—W. R. Tyndale, chairman; George F. Roberts, B. E. Bonar, F. J. Curtis, E. M. Neher, F. B. Steele, F. A. Goeltz, R. T. Richards.

Program Committee—A. A. Kerr, chairman; M. M. Critchlow, secretary; John Z. Brown, F. E. Straup, John R. Llewellyn, E. D. LeCompte.

To Investigate Institutions Caring for Charity Patients—W. R. Calderwood, chairman; M. M. Nielson, Thomas E. Clark.

Auditing Committee—E. D. LeCompte, chairman; A. A. Kerr, L. N. Ossman.

Broadcaster for Hygeia—Willard Christopherson, succeeded by T. B. Beatty.

Community Clinic Committee—George W. Middleton,

chairman; A. J. Hosmer, W. Christopherson, F. E. Straup, J. F. Critchlow, succeeded by A. C. Behle.

Medico-Legal Committee—E. F. Root, chairman; H. P. Kirtley, J. C. Landenberger (three years); A. C. Behle, S. H. Allen, W. S. Ellerbeck (two years); M. L. Lindem, C. L. Shields, F. Leaven Stauffer (one year).

Building Committee—M. M. Nielson, chairman; W. R. Calderwood, Fred Stauffer, E. F. Root.

Medical Liability Insurance Committee—B. W. Black, chairman, resigned March 12, 1924; Sol G. Kahn, appointed chairman, March 12, 1924; F. A. Goeltz, S. D. Calonge.

Aschoff Committee—G. G. Richards, chairman.

Disabled Veterans' Committee—L. J. Paul, chairman; S. C. Baldwin, R. J. Alexander, W. F. Beer, J. U. Giesy.

Receipts

Members paid \$10 each, 202.....	\$2020.00
Members paid \$12 each, 20.....	240.00
Sale of caducei, 26 at \$1.25.....	32.50

Turned over to treasurer.....\$2292.50

The officers wish to thank the members who have served so faithfully on committees and who have co-operated to make the scientific programs a success. All committees have been active, but the Committee on Public Health and Legislation and the Library Committee deserve special praise for their untiring efforts.

At the last meeting in 1923, the by-laws were amended so that members not having paid their dues by February 1, 1924, were considered delinquent and the dues automatically raised to \$12.

On January 28, 1924, the by-laws were amended so that a medico-legal committee became one of the standing committees. The function of this committee is to advise with the defendant in any malpractice suit; to survey the evidence and the elements of the treatment; to appoint witnesses in the defendant's behalf; to adjudicate the question of fight or compromise; to advise with witnesses for the prosecution in malpractice cases; and to arrive at a conclusion as to the merits of such a case. Also to advise with medical experts in personal injury and corporation cases with the idea of promoting substantial justice. To attend the trial as spectators in person or by proxy all cases bearing medical testimony, either "malpractice" or "personal injury"; to listen carefully to such testimony and later review it among themselves; and finally, to prefer charges before the society against any member who makes statements contrary to modern scientific knowledge.

In view of the fact that the society has grown and now is a powerful organization, the present officers recommend that an office of historian be created so that records of the society may be kept from year to year in a concise form.

December 8, 1924.

Minutes of the Salt Lake County Medical Society (reported by M. M. Critchlow, secretary)—The program of the November meeting of the Salt Lake County Medical Society was a symposium on contagious diseases. The first paper was given by William A. Pettit on the "Differential Diagnosis of Contagious Diseases." Scarlet fever, measles, recurrent scarlatina, epidemic exfoliative dermatitis, German measles, drug eruptions, chickenpox, and smallpox, were thoroughly discussed. The paper was discussed by Drs. Beer, Jeidell, Day, and Calonge.

The treatment and sequelae of contagious diseases were dealt with in the paper by William C. Cheney. He took up post-diphtheritic polyneuritis, the various sequelae of scarlet fever and measles, smallpox, and mumps. He discussed the treatment of diphtheria, scarlet fever, and whooping-cough. This very interesting paper was discussed by Drs. John Z. Brown, McHugh, Calderwood, Peterson, Scott, Pettit, Jeidell, Lipkis, Calonge, and Major S. C. Gurney.

Earl Van Cott announced the death of Dr. C. M. Hart. Sol G. Kahn reported for the Committee on Public Health and Legislation, and gave his views on advertising. Fred Stauffer reported for the Committee on the Doctors and Dentists' Building. He exhibited plans for a new building, to be put up on the south side of South Temple, between Main and State, and related the plans for erecting such a building. This building is to be used by doctors and dentists, all except the first floor which is to

be rented. Discussed by W. R. Calderwood, M. M. Nielson, Fred Stauffer, and J. A. Phipps. W. R. Calderwood moved that the society declare itself in favor of the proposed building, and the committee be authorized to proceed with the plans. Seconded and carried. Further discussion by F. S. Scott, M. M. Nielson, F. H. Raley, and J. A. Phipps.

Resolutions on the death of Patrick S. Keogh were read by the secretary. It was moved by Warren Benjamin that the resolutions be adopted. Seconded and carried.

R. O. Porter announced that a railroad company had an opening for a physician out of town, and anybody interested should communicate with him.

A communication was read from Mrs. L. N. Ossman which stated that the Ladies' Auxiliary would hold a tea at the home of Mrs. J. C. Landenberger, December 3, 1924.

Annual Meeting—The annual meeting of the Salt Lake County Medical Society was held at the Commercial Club, Salt Lake City, December 8, 1924. The meeting was called to order by President A. A. Kerr. Seventy-seven members and one visitor were present. Minutes of the previous meeting were read and accepted, with one correction, as follows: "That the society declare itself in favor of the proposed building, and the building committee be authorized to proceed with plans for a building."

A clinical case of hare lip and cleft palate which had been operated was presented by S. H. Allen.

Applications for membership, signed by Lyman M. Horne and J. E. Morton, were read and referred to the board of censors.

President Kerr read an address, setting forth the work done by the society during the past year.

M. M. Nielson and Fred Stauffer reported for the building committee, and three plans were submitted. Mr. Vincent spoke a few minutes on his proposition to erect a \$600,000, eight-story building on First South, between State and Second East, to be partly financed by physicians and dentists, and used by them exclusively, at about \$1.75 per foot.

Thomas Boise of the Hogle Investment Company spoke on their proposition to erect a building on the corner of First South and State, to be leased to physicians and dentists only, at approximately \$1.75 per foot. Discussed by L. J. Paul, Fred Stauffer, and G. A. Cochran. Claude Shields moved that the various propositions be submitted in writing to the building committee, and that the committee should report to the society with their advice. Seconded and carried. M. M. Nielson wished a standing vote of those in favor of the doctors and dentists' building. All stood up.

Fred Stauffer reported for the banquet committee, and suggested that the banquet in honor of Salathiel Ewing will be held December 29, 1924, and the admission to be \$3.

The secretary's annual report was read and accepted.

The report of the treasurer, Joseph E. Jack, was read and accepted.

E. F. Root reported verbally for the Medico-Legal Committee.

W. R. Tyndale reported for the Library Committee, and recommended that \$600 be allowed annually for the library fund. The report was accepted.

M. M. Nielson reported, in place of W. R. Calderwood, for the Committee Investigating Charity Institutions. He read two legal opinions in regard to charging patients who are able to pay for physicians at the Salt Lake County Hospital by outside practitioners. Discussed by F. E. Straup. It was moved that the report be accepted. Seconded and carried.

Sol G. Kahn read the report for the Public Health and Legislation, which was accepted.

L. J. Paul reported for the Disabled American Veterans' Committee, and his report was accepted.

The following officers for the year 1925 were elected: John Z. Brown, president; F. H. Raley, vice-president; M. M. Critchlow, secretary; Joseph E. Jack, treasurer; A. A. Kerr, censor.

Fred Stauffer and F. H. Raley conducted President Brown to the chair. After a short speech by the new president, the meeting adjourned at 10:40 p. m. and refreshments were served.

M. M. CRITCHLOW,
Secretary.

Nevada State Medical Association

W. M. EDWARDS, M. D., Mason.....President
CLAUDE E. PIERSALL, M. D., Reno.....
Secretary-Treasurer and Associate Editor for Nevada

Washoe County Medical Society (reported by Vinton A. Muller, secretary)—The Washoe County Medical Society met in regular session in the rooms of the Chamber of Commerce, Reno, December 9, President R. H. Richardson presiding. The minutes of the previous meeting of November 11, 1924, were read and approved.

Communications—Two letters of condolence, which had been sent to Doctor David L. Shaw in connection with the death of his mother, and to Mrs. John Lewis in connection with the death of Doctor Lewis at the time of their passing, were read to the society, whereupon it was voted that these resolutions be adopted and spread upon the minutes.

Program—Doctor J. La Rue Robinson presented a paper on the extraction of magnetic foreign bodies from the eye by means of the giant electric magnet. He presented three case reports and demonstrated to the members of the society a magnet of his own design which differed primarily from the magnets upon the market, in that it possessed an armature which greatly intensified the pull of the magnetic tip. The magnet is operated by a six-cell storage battery. There were several questions asked by Doctors Albert, Piersall and others, which were in turn answered by Doctor Robinson.

C. E. Piersall, the secretary of our State Association, having recently returned from the meeting of the secretaries of the state medical societies in Chicago, rendered a report on the activities of this meeting.

Election of Officers for the Ensuing Year—The chairman announced that the election of officers for the year of 1925 was in order and called for nominations.

Doctor Tees nominated Vinton A. Muller for president. Nomination was seconded by C. E. Piersall, after which on motion duly seconded and carried, the rules were suspended and the secretary instructed to cast the unanimous vote of the society for Doctor Muller for president for 1925. C. W. West next nominated Doctor Piersall for the office of vice-president, which nomination was seconded by Doctor Pickard, after which on motion duly seconded and carried the nominations were closed, the rules suspended, and the secretary was instructed to cast the unanimous vote of the society for Doctor Piersall for vice-president for 1925. Doctor Piersall next nominated Doctor Horace J. Brown for the office of secretary-treasurer. Doctor J. L. Robinson in turn nominated Doctor Henry Albert for the same office. Doctor Albert declined the nomination, but this was not accepted by the society, whereupon ballots were passed and a vote taken, with the result that Doctor Henry Albert was elected to the office of secretary-treasurer for 1925. C. E. Piersall was next nominated and elected as censor for two years, and C. W. West as censor for three years.

Officers-elect for 1925, therefore, are as follows: President, Vinton A. Muller; vice-president, C. E. Piersall; secretary-treasurer, Henry Albert; censors for one year, S. K. Morrison; censor for two years, C. E. Piersall; censor for three years, C. W. West.

Doctor Ajika Amano, who has filed application for membership in the society, being present as a guest at this meeting, was formerly introduced to the members.

Attendance—Members: Richardson, Albert, Robinson, Walker, Piersall, Pickard, W. H. Hood, Robison, West, Adams, Servoss, Tees, Morrison, Muller. Guest: Ajika Amano.

Before placing the motion of adjournment in order, Doctor R. H. Richardson, as retiring president of the society, gave a short closing speech.

Nevada Medical Bulletin Notes (edited by C. E. Piersall, Reno, Nev.)—You will see in the next few issues of the Bulletin of the American Medical Association what was said and done at the recent conference of the state secretaries.

There are 145,000 M. D.'s in the United States and

only 90,056 members of the American Medical Association, and that 40,000 of them are indifferent about organization and progress is all worth knowing, and the reason for such statistics is most important to us.

At our 1925 state meeting at Elko, we will have a paper about "The Workings of the American Medical Association." This should create interest where now there is indifference.

Read on and see what Dr. Harris said about Direct vs. Indirect Medical Service and Dr. Haggard's message on Periodic Health Examinations. You may obtain articles on and examination blanks for physical examination of apparently healthy persons, from the American Medical Association.

The graduate extension work being carried on by several universities and proposed to be done by the American Medical Association will save us time and money by bringing the teachers to us.

More clinics and case reports are advocated for our county and state programs.

Remember that the American Medical Association is not only a group of officers; it is you and I. What would American medicine be without this organization? Belong and boost. Read the Journal and Bulletin. Subscribe for Hygeia for your clientele, your city library, your politicians.

What subjects do you want presented and discussed at Elko next fall? What subject will you present or discuss? After the program is arranged it is too late to say "Why was I not listed for discussion or a paper?"

California Northern District Medical Society (reported by Charles J. Durand, secretary) — The thirty-seventh semi-annual meeting of the California Northern District Medical Society was held in Sacramento on November 25, 1924. C. E. Schoff, Sacramento, president, and C. J. Durand, Colfax, secretary.

The morning session was devoted to clinics of the Sacramento Hospital:

Surgical, by J. B. Harris, M. D.; A. K. Dunlap, M. D. Medical, by F. F. Gundrum, M. D.; F. N. Scatena, M. D. Urological, by N. G. Hale, M. D.

At the afternoon session, Dehydration in Infancy and Childhood was discussed by Edward S. Babcock, M. D., Sacramento; The Kidneys in Pregnancy, by Alice F. Maxwell, M. D., San Francisco; Practical Points in the Diagnosis of Gastro-intestinal Disease, by Walter C. Alvarez, M. D., San Francisco; Practical Considerations of Sinus Diseases, by Joseph O. Chiapella, M. D., Chico; and Pyelography in Its Relation to Urology, by Nathan G. Hale, M. D., Sacramento.

At the closing business session, the following officers were elected: President, Charles J. Durand, Colfax; first vice-president, J. R. Snyder, Sacramento; second vice-president, Oscar Johnson, Sacramento; third vice-president, Dewey Powell, Stockton; secretary, J. O. Chiapella, Chico; treasurer, O. Stansbury, Chico; board of censors, James H. Parkinson, Sacramento; J. D. Dameron, Stockton; D. H. Moulton, Chico; Charles E. Schoff, Sacramento; George J. Hall, Sacramento.

California Association of Medical Social Workers (reported by C. Ruth Hersey, secretary pro tem.) — At an executive meeting held November 21 at the Children's Hospital, the following new members were elected: Miss Alice M. Keene, Director Health Center, St. Luke's Hospital; Miss M. Meininger, clerical assistant, Mount Zion dispensary; Miss Margaret M. Lindsay, Stanford Women's Clinic; Erla I. Ninnis, Skin Clinic, Stanford Hospital; C. Ruth Hersey, head worker, Medical Clinic, Stanford Hospital; Abbie Carleton Doak, Children's Clinic, Stanford; Ida Schoenitzer, district nurse, San Bruno clinic. Ruth Cooper, County Charities, Los Angeles.

The president reported seven favorable answers to fourteen letters sent to possible candidates to membership in Southern California.

The Army Wants Doctors — On January 12, 1925, an examination will be held for the selection of medical officers of the United States Army. Those interested may secure additional information from any military organization.

Medicine Before the Bench

FINDINGS AND COMMENTS OF THE COURTS ON ACTS AND OMISSIONS OF DOCTORS

[EDITOR'S NOTE—The law reports contain many interesting decisions, involving the reputations and fortunes of doctors. In this column in each issue a brief summary of one or more decisions and comments of the several courts of last resort upon the cases will appear. The matter will be selected by our general counsel, Hartley F. Peart, who, with Mr. Hubert T. Morrow, attorney for Southern California, will contribute from time to time.]

In a case cited with great frequency before the courts, it appeared that the defendants were licensed physicians and surgeons practicing as partners. One of them, Dr. S., amputated the right leg of the plaintiff, the patient dying a short time thereafter. The representatives of his estate secured a verdict before a jury, from which verdict an appeal was taken. It appears that the body of the deceased plaintiff was exhumed at the instance of the deceased's administrator to determine just what the condition of the bones were, and a portion of the bones of the plaintiff were produced in court. The Supreme Court of the state in which the action was tried, in passing upon the case, wrote an opinion which has become a classic. We quote from a portion of it, as follows:

"A final and practical reason for the exception to the ordinary rule in negligence cases is the inherent and inevitable uncertainty of available testimony. The basis of the proof of negligence and of the hypothetical questions to plaintiff's experts is, naturally, the narrative of the family or friends of the patient. Their testimony must ordinarily be unsatisfactory, because of the presence of natural bias, the absence of technical knowledge essential to proper observation, and often the want of opportunity for actual perception, as will presently appear in this case. 'The physician,' said Judge Upton, 'is liable to have his acts misjudged, his motives suspected, and the truth colored or distorted, even where there are no dishonest intentions on the part of his accusers. And from the very nature of his duty he is constantly liable to be called upon to perform the most critical operations in the presence of persons united in interest and sympathy by the ties of family, where he may be the only witness in his own behalf.' This is not necessarily, however, the greatest of the surgeon's tribulations. He is confronted by other uncertainties in testimony greater than those of the human constitution, however fearfully and wonderfully we may be made or act, and greater than those of physical science, however elusive it may be. He is faced by the eccentricities of medical experts. We have no inclination to share in the prevalent and intemperate denunciation of their unreliability and veniality. But if every verdict mulcting a reputable physician in damages must be sustained, if any of his professional brethren can be induced to swear that, assuming the testimony of the family and friends of the patient to be true, the physician had made a mistake of judgment or had been guilty of unscientific practice, then the profession would be one which 'unmerciful disaster follows fast and follows faster.'"

Whose Doctor Are You? — "Nearly every industrial concern employs some doctor," notes Samuel E. Earp (Journal Indiana Medical Association). "Every department store, hotel, fraternal and civic organization also has its own doctor. Most of these physicians receive a nominal fee. A general practitioner is called to see none of these sick persons, and hence he does less practice than in former days, and the newer generation feels the effect more than do those who have been established for a number of years and do work as consultants."

Medical Economics and Public Health

Oregon Defeats Health Insurance—The most complete and drastic scheme of Universal Compulsory Health Insurance yet devised was on the Oregon ballot this year, and was defeated by about three to one. The initiative was craftily drawn as an amendment to the Industrial Accident law, and would have placed the complete control of all agencies of scientific medicine under a political board.

The most interesting feature of the fight, which was carried forward in the usual crusading manner, was the line-up of the forces. *Many so-called health and welfare groups were strongly with the socialists.*

Public Health Ideals—In discussing this interesting topic, as compared with current procedures in England, Doctor R. A. Lyster (Lancet) says:

"The separation of the medical work of the Board of Education from the Ministry of Health is just as complete as ever, *and any alleged unification in that direction is merely make-believe.* It has long been an established ideal of this society that practical unification in this direction is urgently necessary, and I have no doubt that during the coming session the prosecution of this campaign will be continued.

"Local unification of medical services is still a pressing need. All public medical work should be combined in one department under one head, and as far as possible controlled directly through one committee of the local authority.

"At the present time the Ministry of Health and the Board of Education are paying large sums of public money direct to county nursing associations, district nursing associations, welfare centers, and all kinds of voluntary associations, with results that are deplorable from the economic expenditure of public funds and the point of view of efficiency of organization.

"The strangle-hold of the big voluntary associations upon public health work has become one of the dangers of health work. No one appreciates or values more highly than myself the valuable work accomplished by small local associations for after care of tuberculous persons and defective school children, and also by those voluntary workers attached to maternity and infant welfare centers all over the country. These deserve the highest praise and every possible encouragement, but the big associations and "national councils," with whole-time paid officers (a curious kind of "voluntary" work), invariably attempt work which, in my opinion, is far better done by officers employed and controlled directly by local authorities.

"The ideal that public administration should be carried on by public officers and not by voluntary associations can only be departed from with grave danger to the state and to the individual.

"It is a curious mentality which puts a halo round self-appointed members of so-called "voluntary associations" and their (usually unqualified) officers.

"There has been a constantly increasing public danger due to a growing inclination on the part of the central authority to make rules and regulations for all sorts of detailed conditions, and to exercise a supervision over minutiae of administration which, if successfully established, can only result in a degradation of local government. This pernicious tendency is the cause of an increasing irritation on the part of local government officers and local authorities. It is gratifying to be able to record the fact that recently the Prime Minister, and also the Minister of Health, expressed opinions that *the powers of local authorities should be greatly increased, and that there should be greater freedom in local government.*"

Government in Business—"The tendency of government has been, during the past decade or so, to rush headlong into business," writes Paul Shoup (California Journal of Development). "In doing this it has the great advantage over private enterprise, and a great disadvantage as well, in that it does not have to succeed to keep

going. It does not have to justify itself on economic grounds. It may operate a gas plant, run a street railroad, conduct a waterworks, and lose vast sums and yet not be held accountable, for it has the resources of taxation to make up deficits of all kinds, whether the causes of these deficits have been incapable management, profligate wastefulness, or direct dishonesty. Private enterprise must be conducted economically and must justify itself in a business way or fail."

The unanswerable force of this argument still applies if "medicine" is substituted for "business."

"Shall the medical profession vend its products directly to the consumer or shall it sell them to a middleman or third party?" was discussed (House of Delegates, A. M. A.) from the standpoint of what is best for the public as well as from the standpoint of the ultimate effect on the independence and the welfare of the physician as a result of "dealing through a jobber or middleman." This presentation was placed before the House of Delegates by the Judicial Council, because, as stated in its report, lay organizations are offering periodic medical examinations to the public for a stated sum per annum, the examinations being made by physicians who receive from these organizations a much smaller sum than is charged the person examined and who report their findings, not to the examined, but to the officers of such organizations. The council having expressed its disapproval of the methods and the general activities of lay organizations in the field of periodic health examinations was sustained in its position, that *"the proper person to make such examinations and to give advice relative thereto is the family physician, aided, when necessary, by local specialists."* The House of Delegates adopted the following resolutions, after consideration of the matter as a Committee of the Whole:

RESOLVED, That the Committee of the Whole recommends to the House of Delegates that the practice outlined in the supplementary report of the Judicial Council be condemned as against the best interests of the public; and be it further

RESOLVED, That the Judicial Council be instructed to carry on an educational campaign in conjunction with the constituent state associations and to co-operate with other councils and bureaus of the American Medical Association in the promotion of periodic health examinations by family physicians.

If county societies or individual members wish further information, they should communicate with the secretary of the California Medical Association.

Medical Charles Darwins Needed—"What we need today a good deal more than a larger number of research workers is a medical Charles Darwin who could correlate the innumerable detached scientific truths applicable to the practice of medicine already discovered and show us how these can be put to more general practical use," believes E. H. Ochsner. "No one will ever be able to accomplish this important task who does not know medicine from every angle, including the economic angle."

Rockefeller Foundation in a New and Splendid Service—The prefatory note in the first issue of a new series of publications explains the very commendable purpose and the methods by which the Rockefeller Foundation proposes to assist the cause of medical progress by bringing together ideas not otherwise widely available.

"In the present period of unprecedented progress and readjustment in medicine, the problem of the dissemination of information is becoming increasingly difficult and perplexing. In the field of research, productive effort is so abundant that it is quite impossible for an investigator to keep in touch with general literature except through abstracts or reviews. Moreover, lengthy papers, and especially those dealing with problems of administration, equipment, methods and maintenance of laboratories and clinics, are year by year more difficult of publication. This is especially true of contributions in the field of medical education, which, in that they are fundamental to all progress, are in the long run of prime importance. Plans of new buildings, methods of instruction, and experiments in teaching are usually published in local journals or for distribution as commemorative volumes in

connection with a dedication or inauguration of new facilities. Such material, naturally, is not widely disseminated. Likewise, the traveler to other countries, interested though he may be in fundamental problems of medical education and returning with first-hand information of new buildings, and new methods, can reach only a few associates or perhaps the staff of a single institution.

"To avoid some of these difficulties, it has seemed advisable to the officers of the Division of Medical Education of the Rockefeller Foundation to collect and publish from time to time brief descriptions of clinics, laboratories, and methods of teaching in different parts of the world in order that the information in convenient form may be brought to the attention of those most interested. It is hoped that the material may be of assistance to those planning improvements in buildings and methods."

Fake Health Literature—"The New York Department of Health calls attention to the fact that health articles containing advice on how to keep well are now copied as to style by the manufacturers of cure-alls and fake remedies of every description. Under these circumstances it is difficult for the public to recognize the true from the false and be able to protect itself from the snares of the fakir," says the Indiana Medical Journal editorially.

When the Frost is on the Pumpkin and the Fodder's in the Shock is the time for county fairs and with them the inevitable baby contests. Of course, these baby shows put on in the guise of promoting children's health are, for the most part, sponsored by lay persons, but nevertheless in order to give them an air of trustworthiness and finality some very reputable and experienced physicians will be called upon to give their time gratuitously for about a week to the main idea of telling fond mothers whether their pot-bellied youngsters are getting well balanced rations or not, or suffering from anything from hives to infantile paralysis. The big idea is to have a good show that will attract mothers and get a lot of very valuable free advice from some very reputable physicians, and it does not make any difference whether the candidates are able to pay or not.—Indiana Medical Journal.

Dangerous Advice—"Shall the health officer expect the nurse to diagnose communicable disease? Certainly not. But he does expect her to be alert for its possible presence and to report her suspicions for his (health officer's) confirmation, even in cases under the care of physicians," says J. J. Sippy, Executive San Joaquin Health District (Pacific Coast Journal of Nursing). "Physicians resent this at times, but the responsibility is not hers as a nurse but as the health officer's assistant or deputy, and so long as cases of smallpox continue to be diagnosed as 'Cuban itch,' scarlet fever as 'stomach rash,' and diphtheria as 'croup,' we all know that some physicians have their limitations in diagnosis, and that regardless of their sensitiveness they must expect some official intervention if these diseases are to be controlled."

"Even the ultra-conscientious and capable physician may at times be unaware of the prevalence of diphtheria in a locality and thus overlook a mild diphtheritic tonsillitis, the true diagnosis of which the nurse, with her knowledge of other contacts positively diagnosed as diphtheria, can rightfully suspect. In fact, there is symptomatically nothing so obscure about most of the contagions, which the well-trained nurse with keen observation and experience with large numbers of cases is not in a position to diagnose almost as accurately as the average physician whose experience is limited to the occasional case."

The taxpayers of California, in county, municipal, state, and national taxes in 1923, paid considerably more than \$500,000,000 in taxes, or substantially the value of all the products of the soil of the state, fruit, and farming in their raw state.—California Journal of Development.

These figures include the Sheppard Town (er) and Country practice.

The Editor Illinois Medical Journal Believes That what the colleges want and what the country and profession needs is the study of medicine so arranged that a

man of intelligence, of moral principle, and of talent for medicine, can learn how to make sick people well, and how to teach well people how to keep so. There is now too much detail, too much preparation, too much red tape, and an absolute lack of balance. What the public wants urgently is a replenishment of the ranks of old-fashioned doctors. Until this is done the study of medicine will continue to dig its own grave.

Health Examinations—After giving the problem of periodic examinations serious consideration, the committee of the Massachusetts Medical Association, among other important findings, believes (Boston Medical and Surgical Journal) "that unless the profession at large can and does carry out health examinations the real object of health examinations cannot be obtained. . . ."

"While it is true that in some of the more elaborate plans for conducting physical examinations several specialists participate in each physical examination, the committee feels strongly that, as a general policy, it is much sounder if the examined individual is regarded as an entity by one physician rather than as a collection of segments with each of these segments a province of a different physician. . . ."

"The committee would like to see the general practitioner in rather more complete charge of his patients both in illness and in health, not because it might seem to be of benefit to the physician, but because the committee believes that it would be of great benefit to the patient. . . ."

"The committee believes that the medical profession is and must be the very foundation stone of public health, and is inclined to look askance at certain tendencies to separate widely the functions of curative medicine and preventive medicine. Always there will be, of course, specialists and leaders, but the general practitioner should practice preventive medicine as he practices curative medicine."

Hospital Association Among University Students—The University of Illinois (The Nation's Health) claims the most thorough and complete medical service to all students largely at state expense.

The essayist, Joseph F. Wright, believes other universities will copy their system. "The plan for the student health work is carried out in three closely related but distinctly separate departments: the medical department itself, the department for physical training, and the one for general athletics. . . . Most medical attention to students is carried on by the university at state expense, and the work in this department is one of the outstanding things at this university. . . . Most of the work is done by the corps of six university physicians, four of whom attend to the health of the men students, two to the women."

"In connection with the health service there is a hospital on the campus expressly for student use. Many of the students belong to the hospital association, membership in which costs \$3 each semester. This minimum fee entitles the member to all the care furnished by the university hospital, without further cost."

The Need of a Course in Medical Economics in Every Medical College—Today the average medical student is well grounded in the fundamental sciences underlying the practice of medicine. This is acquired at great expense of time and money. The student leaves his alma mater less well prepared in the art of medicine and utterly unprepared to handle those problems which are quasi-scientific in nature, with the result that either he flounders around for from five to ten years until he works out these problems for himself or accepts some poorly paid position in a health department or industrial concern or gives up in despair and leaves the medical profession in order to enter some other vocation.—E. H. Ochsner.

Yes, We Do Not Practice Medicine—An essayist (Pacific Coast Journal of Nursing) illustrates how nurses do not practice medicine, by telling of an instance where a teacher reported to the nurse that pupils had an itching eruption.

"Upon inspection of the pupils, the nurse found that eleven out of fifteen pupils had either in-

petigo or scabies. What was she to do? The parents would not take these children to a physician nor would they have a physician come out—\$70 for scabies—it isn't done. The nurse had gotten permission from the county physician to use ammoniated mercurial ointment for impetigo, sulphur ointment for scabies, and always had a supply with her for such emergencies as this. The children usually paid from 10 to 15 cents for a very small box of the ointment. In this case the school district paid the cost of the ointments. As you know, these small schools are usually made up of four or five families; therefore, it was not difficult for the nurse to make the necessary home visits to teach the mother how to carry out the treatment for impetigo and scabies."

If this is not diagnosing and treating disease and thus practicing medicine, what is it?

Educated licensed physicians do not always find it so easy to make a correct diagnosis of all itching skin eruptions, nor do they all take chances with ammoniated mercurial ointment when the diagnosis is uncertain. Sulphur ointment has the virtue that it is harmless.

All worthwhile physicians fully appreciate the tremendous value of public health nursing, and they have the greatest admiration for the splendid work the vast majority of these women are doing. Doctors, better than others, realize the personal sacrifices that the pioneers in this comparatively new service are making, and always extend the hand of helpfulness and encouragement to these nurses.

Physicians do feel that public health nurses have enough to do in this broad and hardly explored field in which they have been educated and trained to serve, without attempting to diagnose and treat disease.

Compensation Insurance Fund Pays Dividend—The Industrial Accident Commission has authorized the return of an average of 30 per cent of the premiums collected from policy-holders during the year 1924. The dividend for the current year reflects a successful conduct of the fund that is shared in by its patrons. Notices of return premium will go out about January 1, 1925. During its existence, extending over a period of eleven years, the fund has returned to its policy-holders \$8,300,000.

This year's volume of business is the largest in the fund's history.

Telephone Amenities and Otherwise—An editorial under the above caption in Northwest Medicine, November, 1924, evidently struck a responsive cord in the hearts of several of our readers. The closing paragraph of the editorial reads:

"If anyone is to be kept waiting at the telephone, the one who calls should do it and not the one who receives the call. It might be well if physicians would bear in mind that good manners will be better served if they will allow their attendants to ring up others only after they themselves are ready to answer. Or, better still, as soon as the other fellow's attendant has indicated that he is on hand to take the telephone, and themselves do whatever waiting is necessary."

Some Things the Mail Man Brings Doctors—One of our members dropped into the editorial office the other day and handed us the odds and ends of the things that had come to him through the United States mails recently.

We note the following abstracts:

Case 1—*Called a West Union Tel-Gram*—"Long Beach, Calif. Many doctors and 80 to 90 per cent of the patients treated with concentrated orchitic solution—goat, ram or monkey type—have decreed that your interest should be eminent. Return this Tel-Gram, designating quantity desired of Concentrated Orchitic Solution—goat type, ram type, monkey type."

Case 2—*Form Letter on the Stationery of an M. D.*—"Mr. — suffered a hemiplegia of the left side, January 13, 1924, and the doctors there said nothing would do any good. April 16, I gave him 20 cc. more of the Concentrated Orchitic Solution. Today, April 19, his blood

pressure is normal and he is very much improved. Walking without his cane."

Case 3—Was an announcement to the effect that the chiropractors were going into politics!!?

Case 4—A "Catechism of the Electronic Methods of Dr. Albert Abrams."

Case 5—An invitation from —, A. M., M. D., on stationery of "The Birth Control Clinical Research," to send \$1 for "Birth Control Methods."

Case 6—A. D. O., M. D., announces the removal of his offices and invites his friends to a two-day pre-view of his new offices.

Case 7—Announces the opening of the — Laboratories "Under Medical Supervision."

Case 8—Letter inviting purchase of lottery tickets. (Letter forwarded to postoffice authorities.)

Case 9— — Foundation Clinic. They want to cooperate with doctors."

Case 10—A "personal puffery" bulletin of the type now issued by certain hospitals, health centers, clinics and individual physicians, telling other doctors all about me and my methods.

Case 11—An invitation to buy "six essays on sex" and "How and why we are made."

Cases 12, 13, and 14—Advice about investments and urgent invitations to buy—and—and—

Some Day We Will Meet Here—Maybe—What, if any, common ground is there for the physician, the health officer, and the layman to meet upon? This has been a cause for much discussion, and apparently a partial answer may be found in periodic medical examination of the apparently healthy person. This is a field in which the health officer can preach the lowering of morbidity and mortality rates; the health enthusiast picture a perfect future race; the physician exercise his diagnostic technique and develop along therapeutic lines; and the average citizen, the apparently healthy person, participate with reasonable expectation of a fair return for the effort.

The health officer has been mainly active in mass health promotion and protection; the physician steeped in disease diagnosis and treatment; the layman interested in his pains and symptoms. *All must become adjusted to personal medicine—the health officer as the promoter, the physician as the guide, and the layman as the willing seeker after health.*

"The private physician is more or less familiar with the patient's interests and environment and, therefore, better able to render health service to the individual than is the case when the examinee comes as a stranger to a strange physician. This is important—the success of the health examination depends more upon the rapport between physician and examinee than does a diagnostic examination."

"The medical technique used in making health examinations differs in no essential from that of any thorough physical examination. The points of view of physician and examinee and their attitude toward the examination, are, however, essentially different from the usual relationship between physician and patient."—A. N. Thompson (The Commonwealth).

A Microscopic Study of Mercury Absorption From the Skin—Microscopic examination made by Karl G. Zwick, Cincinnati (Journal A. M. A., December 6, 1924), of intact animal skin, to which mercury, in the form of mercurial ointment had been applied by inunction, established: 1. The presence of globules of mercury: (a) in the infundibula of the pilosebaceous follicles; (b) in the orifices and excretory ducts of the sebaceous glands. 2. The absence of globules of mercury: (a) in the intact epidermal layers that are not constituents of the integumentary appendages; (b) in the cutis vera. Microscopic findings lead Zwick to conclude that: 1. Percutaneous absorption of mercury, following inunction of animals with mercurial ointment, takes place preponderantly from the material deposited in the pores, consisting of the orifices of the hair follicles and of the excretory ducts of the sebaceous glands. 2. Percutaneous absorption of mercury is not materially influenced by removing from the intact skin the excess of mercurial ointment deposited on it during inunction, because mercury does not penetrate into or through the intact epidermis.

THE GILCHRIST CHLORINE EJECTOR

For measuring and distributing of Chlorine Gas used in treatment of respiratory diseases

For a period of five years the officials of the National Research Laboratories have watched the progress made by the Medical Department of the Chemical Warfare Service of the United States Army, in the use of Chlorine Gas as a therapeutic agent in the prevention and treatment of respiratory diseases.

This apparatus was devised and perfected by Lt. Colonel H. L. Gilchrist, Medical Corps, United States Army, and has been in constant use since February 1, 1924, i. e.

One—In the chlorine gas chamber established in the Capitol Building, Washington, D. C., where many senators, representatives and other high officials have been treated.

One—In the chlorine gas chamber established in the Munitions Building, Washington, D. C., where forty to fifty persons are receiving treatments daily.

One—In the office of the Surgeon General, Washington, D. C., where President Coolidge, hundreds of army officers and members of their families have been treated.

A Firm Belief in the Gilchrist Chlorine Treatment

The Gilchrist Chlorine Ejector enables the operator to measure accurately proper quantities of Chlorine gas for distribution in a room where the atmosphere is to be medicated, and it also provides for the regulation of the outlet flow. It has no complicated mechanism. It is not dependent upon an unseen electrical flow or generation, and the exact amount of gas to be given is seen before it is liberated. This apparatus is easy to operate and is fool-proof.

In the minds of official Washington, there is a secure and firmly grounded belief that the Gilchrist Method of administering chlorine gas is most efficacious in the prevention and treatment of respiratory diseases.

Hundreds of Government employes, congressman, senators, cabinet officers, and the President are reported to have been benefited by the Gilchrist Method of Chlorine Treatment.

PARATHYROID

Powder and Tablets 1-20, 1-10 Grain

—And—

Parathyroid and Calcium Tablets

1-20 Grain Parathyroid

2½ Grain Calcium Lactate

Parathyroid preparations are indicated in Paralysis Agitans, Tetany, Indolent Ulcers and lesions that refuse to heal.

These parathyroid products are carefully made from fresh normal glands of young cattle.

Pituitary Liquid, standardized, in ampoules, surgical 1 c. c., obstetrical ½ c. c. Premier preparation of Posterior Pituitary.

Anterior Pituitary powder, 2 and 5 grain tablets. Pituitary whole gland, powder 1 and 2 grain tablets. Posterior Pituitary, powder and 1-10 grain tablets.

CHICAGO

MEDICAL STRAWS

By THE EDITOR

Experience is fallacious and judgment difficult

Professional Pitfalls—The Council of the Union (a British medical defense organization) states that the number of cases (malpractice) with which it dealt has increased and that there is reason to believe that charges against medical practitioners are becoming more frequent, possibly because certain actions lately heard in the High Court have encouraged patients to seek to obtain damages from their medical attendants when recovery has been more prolonged or less complete than they imagine it should have been.

Federal Government Wants More Salaried Doctors—They want them of the Grade A and Grade B classes, and they propose to pay them from \$1680 to 3000 a year. In order to make these remarkable salaries still more intriguing they offer maintenance in some of the least desirable of the positions.

The Gamest Guy in the World (Meigs O. Frost, Collier's), is a beautifully told story of fortitude, patriotism and medical service that bristles with morals and statements for exhausted SERVICE batteries.

THAT there is an ebb and flow in the tide of syphilitic morbidity should always be taken into account by those who are studying morbidity rates of venereal disease, and especially by public health officers who are attempting to arrive at conclusions regarding the value of laws compelling the reporting of these diseases.

Too many vital statisticians are losing track of the tides, in frantic efforts to measure individual waves.

The Doctors We Patronize—The examining physician of the Y. W. C. A. in Pasadena reports that, in examining 1200 women and girls, she asked them the names of their attending physicians. Seven hundred and seventy-two of these young women patronized osteopaths; 120, chiropractors; 183 christian scientists, and 125 educated physicians.

Is this a logical consequence of our several years of "health education" for everyone?

Who Are "We"?—"Shall the nurse perform vaccinations or immunizations?" asks J. J. Sippy, M. D. (Pacific Coast Journal of Nursing) and then, answering the question, says: "Without authorization, no. But as far as actual technique is concerned, WE are most of us willing to admit that *she is usually as capable as the physician.* (Italics ours.) It has seemed somewhat contradictory to me that many physicians will entrust the care of serious wound infections to their office nurses and yet resent the performance of a smallpox vaccination by the public health nurse."

"Yellow Medical Journalism"—Doctors are still neophytes in the field of popular journalism, and already some writers are calling them "Princes among yellow journalists."

It is said that some doctor writers, with more newspaper notoriety than professional reputation among their colleagues, are occupying the field of flamboyancy, the spectacular and the personal bombast now all but vacated by the patent food, patent medicine, and "get-rich-quick Wallingford" fakirs.

How much truth is there in this charge?

Osler Said Cannily—"It is more important to know *what kind of a patient* has pneumonia than it is to know *what kind of pneumonia* the patient has."

A New Spirit in Health Work—A writer, in a recent issue of the State Board of Health official publication, says:

"Concerted effort is needed to correct the false impression that is prevalent in some sections of this state that the public health nurse is violating the Medical Practice Act by making diagnoses and treating disease. Wherever wilful misrepresentation is made, and where false charges are brought, *vigorous retaliation should follow.*"

Several Departments of Government Still Advertising for More Doctors—The Public Health Service; the Indian Service; the Coast and Geodetic Service; the Panama Canal Service; and the Veterans' Bureau are all advertising for more doctors. The opening salaries (?) offered are from \$140 to \$250 per month. Those interested should address the United States Civil Service Commission at Washington.

Regents of University of California Uphold Scientific Medicine—Protection against smallpox by vaccination is still one of the *requisites* of students at the University of California. The strenuous campaign of certain internists to change the "*requirement*" to an "*optional*" failed. It is said that the only regents who voted for the backward step were the Governor of California, Chairman of the Board, and J. O. Hayes from San Jose, appointed regent by Governor Richardson.

The Things That Count—In the every-day work of medical practice, as in the world of business, the qualities of absolute honesty, integrity, and consistent industry are far more important than brilliance of intellect or flashes of genius, valuable and stimulating as are these latter traits.—E. J. G. Beardsley, Journal New Jersey Medical Society.

Prevention and Cure—One official state health bulletin now boldly places in prominent headlines its program of public health betterment to include *Prevention and Cure.*

Heretofore, all official health bodies have denied their intention to include the practice of personal medicine as part of the public health medicine program.

Fewer and Better Books—"A plea for fewer and better books was applauded at the annual convention of the American Booksellers' Association," says The Nation's Business. "Too many 'pot boilers' are coming from the printing houses, to the discouragement of book reading and book owning."

This should apply and must apply to the medical books. Why not eliminate some of the medical "pot boilers" at least?

Why Do Doctors Assist Laymen in the Practice of Medicine?—Medical men probably never will overcome the dabbling of lay persons in purely medical problems, but we can put a crimp in such activities by refusing to have anything to do with them. Medical problems should be solved by medical men without the intervention of lay persons who interest themselves for commercial reasons or to exploit themselves.—Journal of the Indiana State Medical Association.

Sauce for the Goose

—Physicians receive bills the first of every month from everyone to whom they owe money. . . .

—A doctor's worst enemies, and the ones most apt to speak ill of him or even give him trouble without cause are the persons who owe him money and can pay but will not, and some of the charity patients who long have been accustomed to dependency, are not ashamed to ask for assistance and are very exacting.

—If the doctor's services are donated, the patient should understand that they are being donated and that he is accepting charity.—Lovett Morse.

POTTENGER SANATORIUM

FOR DISEASES OF THE LUNGS AND THROAT

Monrovia, California

AEROPLANE PICTURE OF THE POTTENGER SANATORIUM

Situated on the southern slope of the Sierra Madre Mountains at an elevation of 1000 feet. Winters delightful, summers cool and pleasant. Thoroughly equipped for the scientific treatment of tuberculosis. We have established, in connection with the Sanatorium, a clinic for the diagnosis and study of such non-tuberculous diseases as asthma, lung abscess and bronchiectasis.

Los Angeles Office: 1045-6-7 Title Insurance Building
Cor. Fifth and Spring Streets

For particulars address:

POTTENGER SANATORIUM,
Monrovia, California

Ain't Science Wonderful?—Put the average layman in a clean white hospital, give him a good-looking nurse, let him talk with the wise interne, meet the affable surgeons, and let him be entertained by nine experts from Tuesday to Friday; let him be thoroughly examined from the anterior pituitary body to the posterior coxigeal peduncle; take a specimen of each of his body fluids for inspection; x-ray him; get his blood pressure; use the ophthalmoscope, the proctoscope and the microscope; basal-metabolize him; strip him, pound him, punch him, and note his reflexes; take his history from the time his ancestors began to wear clothes up to the last five minutes; make more fuss over him than he expects to get in eternal glory; diagnose him; note his bald head, bias squint, defective septum, turbinates, hyperthyroidism, abscessed molars, submerged tonsils, cholecystitis and chronic appendicitis; operate him, and he will come back home cured—and broke. The family physician who can measure up to that man's estimation of what a doctor should do, has most country doctors bested. That man is so wise that he is rotten. He wants his family doctor to bichloride his hands before he feels the baby's belly. For a while, he blows his nose on antiseptic gauze, and spits in formaldehyde while reading his fumigated newspaper.—Joe E. Dildy, M. D. (Texas State Journal of Medicine).

As President Vincent, Rockefeller Foundation, Sees It—“The well-trained, properly equipped, experienced general practitioner of ability, character, personality, is a fundamentally valuable person. He is a good diagnostician. He sees his patient as a whole. He knows his peculiarities and circumstances. He can decide when to refer him to a specialist and when to protect him against the very real danger which is threatened by a narrowly specialist point of view.”

Rickets as Influenced by Diet of Mother During Pregnancy and Lactation—Judging from their experiments, Alfred F. Hess and Mildred Weinstock, New York (Journal A. M. A., November 15, 1924), conclude that rickets cannot be prevented by improving the diet of the mother, previous to pregnancy, during pregnancy, and throughout lactation, although it can be mitigated to a certain degree. Supplementing the diet of the mother for two generations also failed to render the young refractory. Infants were not protected by giving the mother cod liver oil during the last two months of pregnancy. On the other hand, the fact that premature infants are markedly susceptible to rickets shows that prenatal nutrition does play a role. A consideration of the experimental evidence, of clinical tests, of the susceptibility of bottle-fed compared to breast-fed babies, and the striking seasonal incidence leads to the conclusion that rickets is mainly of postnatal origin. Although its incidence and severity may be influenced by improving the nutrition of the mother, our main efforts should be directed toward improving the environment and nutrition of the infant. Until these postnatal factors are corrected, we cannot hope to prevent rickets.

What Are You Doing About This?—“But I (Frank J. Monaghan, Long Island Medical Journal) want to say, as a result of my observance (of periodic medical examinations) that, if we are to have absolute success in this particular endeavor we are now taking up, *it is going to remain with the individual physicians to see that this thing is absolutely carried out to its logical conclusion*, and that means that any examination that any physician undertakes to make for this purpose must be made so particular, so painstaking, with all the assistance that science can give him, that there shall be no question that when he has finished with the examination of any particular case, he will be able to say he has made 100 per cent examination, and be practically sure he did it.”

This Sterilizer Boiler Will Never Corrode

The boiler of the PELTON Indestructible Sterilizer is stamped in one piece from a heavy sheet of seamless copper, a material unaffected by the chemical and mineral impurities in water. Pitting and corrosion are impossible.

Because this one-piece construction eliminates the use of solder, the PELTON sterilizes by dry heat as well as by boiling. Your instruments are thoroughly dried after boiling, and so protected from rust. Their temper is guarded by a positive automatic cut-off.

A catalog awaits your request.

"Consistency, Thou Art a Jewel"—Under this title the Illinois Medical Journal, speaking editorially, says: "It is remarkable that in industries most threatened by government ownership, many of the leaders do not seem to care what becomes of the other fellow in the same boat, provided they themselves keep a few feet ahead of the socialist sheriff with his writ of ejectment. The real issue in America today is not whether certain industries shall be socialized, but whether the institution of private property shall be maintained. It is too much to expect people to take seriously protestations of one industry against government ownership when we find the leaders of that industry advocating government ownership of somebody else's business. There is no more reason why medicine should be socialized than there is for the socialization of every other industry. People are just as much entitled to free groceries, free clothes, free shoes, and every necessity of life as there is for free medical attendance."

The Home Is the Only Important Teacher in Sex Matters—The home is the first school in which the facts of sex are inevitably being revealed to the child. If the home drama, with respect to sex, is clean and inspiring, solid foundations for sound sex character are being laid (Social Hygiene). *If the home fails in this respect, nothing can ever wholly make up for the loss.* No matter how correct sex-teaching in the home may be, if the atmosphere, inferences, remarks, and example, with reference to sex, are out of accord with the teaching, the teaching will not avail.

The fees for an insanity commission, witness-fees in court, and insurance examinations, as a rule, compensate a physician so poorly that, if he sacrifices his time to give them his attention, he belongs to the underpaid.—S. E. Earp (Journal Indiana Medical Association).

What people want is a doctor who will utilize every means to determine the cause of their sickness and to know how to effect a cure.

ALQUA

THE IMPROVED
ALKALINE WATER

ALQUA WATER contains the alkaline salts found normally in the human body. Physicians will find it invaluable where alkaline treatment is indicated. Not only is it very effective in the treatment of most acute and chronic diseases caused or accompanied by acidosis, but it is an ideal preventive, in that it neutralizes destructive acid by-products in the system.

GLACIER SPRING WATER with which Alqua is prepared, originates in the upper glaciers of Mt. Shasta, California, U. S. A., (Elevation 14,442 ft.) Its great purity without artificial treatment, renders it especially suitable for affinitization with the added salts, thus forming a combination that is remarkable as an alkaline water. Glacier water is released from the earth at Shasta Springs where it is put into block-tin lined carriers and transported to the Company's laboratory where the alkaline salts are scientifically added under the directions of an expert chemist, thereby creating, through the united efforts of science and nature, the wonderful medicinal virtues of Alqua Water.

The Management of an Infant's Diet

Malnutrition, Marasmus, Infantile Atrophy, Athrepsia

Mellin's Food
Skimmed Milk (1% fat)
Water

8 level tablespoonfuls
9 fluidounces
15 fluidounces

This mixture contains 56.61 grams of carbohydrates, thus supplying material that is utilized rapidly for heat and energy. The predominating carbohydrate is MALTOSÉ, which has the highest point of assimilation of any of the sugars, is immediately available as fuel and may be safely given in comparatively large amounts. The daily intake of protein from the employment of this formula is 15.54 grams, an amount calculated to be sufficient to replace depleted tissues and to provide for new growth. There is present in the mixture 4.32 grams of salts for replenishing inorganic elements.

The suggested modification furnishes nutrition in keeping with the character and amount of food elements best adapted to the particular demands of infants in an extreme state of emaciation and serves well as a starting point in attempting to meet the nutritive requirements of these undernourished babies.

Mellin's Food Co., 177 State Street Boston, Mass.

Just the Thing You Have Wanted For Some Time!

The way to provide hospital service for everyone in your city at a very small cost to them and without loss to yourselves.

Your information desk and welfare department should not only understand the National Surety Hospital Bond but should endeavor to sell the bond to people in your town.

Just think! A family of three people can be assured of Hospital Service up to \$70.00 a week for the small sum of ten cents per day.

A number of hospitals in San Francisco have tried selling Hospital Bonds over their counters and through their welfare workers, and found it to be very profitable business not only from the sales standpoint but it also insures the people of ample hospital service when they need it and assured you of your money weekly.

Fill out the enclosed coupon with the name of the party you want us to explain the Hospital Bond and we will see that they have complete data on same.

Progress and Scope of Quartz Light Therapy and the Hanovia Quartz Lamps

The Alpine Sun and Kromayer Lamps

Pioneers in 1905

The Standard of the World Today

These Lamps have the entire quartz mercury anode type of burner, *made in our own plant*, the therapeutic ability of which has long since been proven, by the service rendered to the Medical Profession.

The Lamps themselves are simple of operation, with extreme cheapness when in use, and have the maximum intensity of quartz rays.

Quartz Light Therapy is a subject that every prominent physician should investigate at once, and for this purpose we have some very interesting literature in Asthma, Hay Fever, Rickets, Tetany, Eye, Ear, Nose and Throat, Dermatology, Gynecology, Tuberculosis and others.

ACIDOSIS

By some investigators ACIDOSIS has been designated as a diminution of the alkalinity in the blood; by some as an excess of acid in the blood; by others as a lessening of reserve supply of fixed bases in the blood.

If the acid combining power of the blood is impaired BY A LACK of the alkalies, sodium bicarbonate and sodium phosphate, and may be built up by the process of food ingestion, *may we ask* attention to CALSO WATER, which is rich in the potential alkalies.

BOOK REVIEWS

This column is conducted solely in the interests of California and Western Medicine readers. Critical comment, favorable and unfavorable, purely from the standpoint of the interests of the medical reader, will be made about books selected from the larger number acknowledged in the Books Received column. The advertising columns are open to book publishers who wish to make additional statements about their publications.

Practical Electrotherapeutics and Diathermy. By G. Betton Massey. 401 pages. New York: Macmillan Company. 1924.

The publication of this work on the utilization of electrical modalities in medical treatment by a physician so capable and experienced in electrotherapeutics is distinctly worth while.

Too often the electrical measures are considered immaterial and bordering on quackery. The inability to estimate electrical treatment so definitely as calculating blood cells or the chemical analysis of urine, influences many physicians to under-rate the value of this physical method. Doctor Massey in a clear, practical manner first describes the various forms of medical electricity and their scientific application in medical treatment and then, chapter by chapter, by "statements in the concrete for complete comprehension," imparts information which the physician will find applicable in a host of medical problems.

The importance of inducing active hyperemia is now generally recognized and the author predicts "that diathermic hyperemia will be found to be useful in the acute, grave bacterial infections of internal organs, such as pneumonia, peritonitis, etc., when physicians perfect the technic and indications."

H. L. L.

"Wise men school themselves against fretting," says Bruce Barton, in the Red Book magazine. Emerson, having attended a meeting in Boston which went very much against his liking, arrived at his front gate in Concord in a rebellious mood. He stopped and looked up at the stars, which had gazed serenely on so many fretful folk. 'Why so hot, my little man?' they signaled. Emerson chuckled at their message and went peacefully to bed."

For Thirty Years

In the *seven States of the Pacific Coast and slope, two generations* of men, most particular of their appearance, and *distinctive in dress*, have invariably turned to us for their made-to-measure

Dress Shirts, Tuxedo Shirts, Sport Shirts, Neckwear, Lounging Robes, Slumber Robes, Underwear, Pajamas.

ALUM ROCK SANATORIUM

FOR THE TREATMENT OF TUBERCULOSIS IN ALL ITS FORMS

The Sanatorium adjoins Alum Rock in the eastern foothills of San Jose, 900 feet above sea level, and overlooks the entire Santa Clara Valley. The climate is ideal throughout the year. The distance from San Francisco by rail or motor is fifty miles. The buildings are situated in the center of a beautiful ten-acre tract under cultivation. A hedge of eucalyptus partly surrounds the place and there is a great variety of flowering shrubs, citrus and pine trees. The aim of the Staff is to give tuberculous patients intensive individual treatment and each case will be carefully studied with this end in view.

CALCREOSE

*Samples of Tablets
on Request*

CALCIUM AND TUBERCULOSIS

CALCIUM starvation has been suggested by phthisiologists as a factor in the etiology of pulmonary tuberculosis. By prescribing CALCREOSE some of the needed calcium may be supplied.

CALCREOSE (calcium creosotate) is a mixture containing in loose chemical combination approximately equal weights of creosote and lime. It has the pharmacologic activity of creosote as used in the adjuvant treatment of tuberculosis, but differs from creosote in that it apparently does not have any untoward effect on the stomach.

POWDER—TABLETS—SOLUTION

THE MALTBIÉ CHEMICAL COMPANY
NEWARK, NEW JERSEY

"The all-important factor for the evolution of species of animals, and the evolution of species of diseases, i. e., the development of disease and of pathogenic micro-organisms, is the variation in the host," says J. Madison Taylor and Henry Winsor (Western Medical Times). "The most important factor in the cause or cure of disease, is, therefore, the variation in the host. The question of most importance is: how and why do these variations arise in the host. How can they be modified to suit their immediate environment? This must be the factor for the cause, prevention and cure of disease."

You ought to choose both physician and friend not the most agreeable, but the most useful.—Epictitus.

Do You Treat Your Patients or Their Disease?—

"Is it because we are taking too much interest in the patient as a 'disease' and not enough as a human being that we are getting away from the personal touch that characterized the old-time family doctor?" asks the Journal of the Missouri State Medical Association editorially "To make a correct diagnosis may be gratifying. Too many physicians may think their duty is performed when they have solved a difficult case. The old-time doctor stayed with his patients till the patient either died or got well."

"The 'Why' of Lay Education"—Writing under this title, Charles J. Whalen (Illinois Medical Journal) says: "Besieged by the cry of the charlatan, the sick man hears and believes to his own undoing. He does not know the difference between what is false and what is true. He hears vaguely of wonderful progress and miraculous 'research discoveries' made by medical science. But taking advantage of the dignified reticence of medical science, the charlatan seizes upon the name, and perhaps the method, of specific progress and uses it to delude the ill and unwary."

There is one sure way of protecting instruments

— have water in the sterilizer

Never let the water get low if you can help it. But when you *do* forget, you will want a sterilizer that is made never to boil entirely dry. Water left in the bottom after the shut off operates is the only protection your instruments can have against being burned.

The CASTLE sterilizer shuts off before the water is all gone, and it is the only one built that way. Wet instruments are better than burned ones.

*No. 1316-A
Both sterilizers have
the cut-off that
works before the
water is all gone.*

The illustration shows an "American" Flat Work Ironer, part of the "American" equipment in the hospital laundry.

"The Saving is \$3,000 a year"

Previous to the year 1920, The Hospital for the Women of Maryland—containing 134 beds—was not provided with a laundry.

Then this hospital began to do its own laundering, in an "American" equipped plant of its own.

Now M. M. Garner, R.N., Superintendent, writes as follows:

"The result of having all laundry work taken care of in the Institution has proved most satisfactory from every standpoint. It is estimated that the saving in actual cash is about \$3,000 a year."

"American" laundry machinery has proved equally satisfactory in many other representative hospitals and institutions. A staff of "American" experts is always ready to advise you concerning any laundry problems which you may have. This service is offered without any obligation to you.

AMPOULES

OF

Chlorine Gas

"ROEHLING"

USE WITHOUT MACHINE

A method of releasing chlorine gas in a measured dose for use in the treatment of certain respiratory conditions. Each ampoule contains a measured dose of pure dry chlorine gas suspended in an inert harmless liquid solvent.

No machine is required for its administration. Simply pour the contents of the ampoule into a shallow dish placed in the center of a closed room. The ampoule is measured for 1000 cubic feet, from which a variance of one to two hundred feet has been found to be permissible. There can be no danger of an overdose.

AMPOULES OF CHLORINE GAS "Roehling" afford a clean, safe, easily handled, and economical method of administering chlorine gas. They sell for \$4.00 per dozen, and can be obtained from any physician's or hospital supply house in the United States or Canada, or will be shipped direct from us upon receipt of the price or authority to ship C. O. D.

PATIENTS EAT IT
BECAUSE THEY LIKE IT

ZED

You don't have to urge a patient to eat ZED for the good of his health. Once he tastes ZED he is quite willing to eat it for the simple and self-sufficient reason that he *likes* it.

Yet ZED has every nutritive and laxative element science demands in a health-biscuit. Whole wheat and bran are used to supply "roughage." The clean, wheaty flavor prevails and covers the coarseness of the bran. Milk, natural fruit and vegetable extracts serve as a taste-vehicle for the coarse cereals and furnish laxative and mineral elements besides.

It is because ZED is so delicious, quite apart from its laxative and healthful qualities, that more and more practitioners are using it with fine success in the treatment of any condition that points to intestinal stasis.

May we send you a full-sized trial package free?

Zed Corporation • San Francisco

*Every grocer has, or can easily get, ZED
Biscuits for your patients*

GEORGE C. BUTLER, *Proprietor*

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of

them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the United States.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) \$45.00 per week and upward.

ADDRESS **LIVERMORE SANITARIUM** LIVERMORE CALIF.

Nature May Be Interpreted, but Not Led—"Refuse to admit each fact until supported against every point of fallibility that your own most hostile critical mind can bring against it," urges William Seagrove Magill (West Virginia Medical Journal). "Never attempt to lead Nature, but learn to accept and rightly interpret the replies she may reveal to your assiduous inquiry and closest observation of experiment."

A Question of Medical Honor—"The exclusive right of the medical profession to sign death returns entails an important duty. Even the youngest physician owes it to the honor of the profession and to himself for the benefit of his future practice to make a sincere effort to determine the exact cause of death in any case where he must sign the death return," says the Rhode Island Medical Journal editorially. "If an autopsy is necessary it should be performed. A death return should be an absolute statement of fact and not a product of imagination."

New Grave-digging Tools—"You doctors are telling us all the time about people digging their graves with their teeth," says John L. Belford (Long Island Medical Journal). "Well, now the teeth are not the only weapons, the only instruments, we employ to dig our graves. We dig our graves when we lose control of ourselves to that degree that we abuse the mechanism with which the good Lord has equipped us; and no one has a right to do that."

What Is Your Purpose?—"You gentlemen of the medical profession are trained along a particular line which is one of the most useful lines that can be imagined; and in your work you have it in mind not merely to make a living, not merely to acquire a reputation; but you have it way back in your head to do good to humanity, which is the particular purpose for which you were sent here," says John R. Belford, in an address on "The Church in Community Health."—Long Island Medical Journal.

Pollen Asthma

SEASONAL asthma is usually caused by pollen sensitivity. Even in perennial asthma, pollens are frequently found to be primary or secondary causative factors. Hence, it is now recognized that in the diagnosis of asthma, pollen proteins should be used in association with food, epidermal, bacterial and other proteins. Diagnostic pollens are, however, of particular importance when testing cases whose symptoms are accentuated during the pollinating seasons.

This Book on Artificial Feeding is Yours for the Asking

Just off the press. Contains a practical simple method based on the actual metabolic requirements of the infant.

It contains formulas, illustrating how cereals may be employed in safe and proper quantities, through the use of Dennos, a cereal milk modifier.

The addition of Dennos to Milk—has three distinct advantages—

1. Dennos is an aid in breaking up the curd into fine, flocculent particles.
2. Dennos is of value in the proper assimilation of salts, especially calcium and magnesium.
3. The method of preparation is more simple than the usual manner in which cereal feedings are prepared.

A Compact, Yet Practical X-Ray Outfit for the Physician's Office

Victor Stabilized Mobile
X-Ray Unit

Here is an outfit which has solved the problem for hundreds of physicians who desire compactness as one of the first requisites in an X-Ray outfit, without any sacrifice in the quality of radiographs produced, and combining simplicity and convenience in operation.

The Victor Stabilized Mobile X-Ray Unit is a complete, self-contained unit incorporating the Victor-Kearsley Stabilizer—an exclusive Victor feature—which standardizes technique and insures good radiographs consistently. This Stabilizer is one of the most important X-Ray developments in the last decade, having made possible the wider use of X-Rays by physicians, thru greatly simplified control and uniform results.

Note the large rubber-tired casters which make it a truly mobile outfit, easily shifted around the room.

Hospitals, too, are supplementing their stationary X-Ray equipment with this Mobile Unit, finding it ideal for bedside work in cases where the patient cannot be conveniently moved to the X-Ray laboratory.

What are your X-Ray requirements? We can help you meet them in the most practical way

Post Operative Nutrition.

The difficulty often experienced in re-establishing normal eating habits after surgical work is greatly minimized by the use of Rockridge Water. It is readily accepted by the patient because of its refreshing palatability. Its mineral contents are so combined as to cause no gastric disturbance, and its alkaline reaction in the tissues is most desirable in promoting a rapid convalescence.

Role of Monilia Psilosis (Ashfordi) in Experimental Sprue—Experiments conducted by Lawrence Weld Smith (Journal A. M. A., November 15, 1924), support Ashford's theory of the specific etiology of sprue as due to monilia psilosis by the production in guinea-pigs of a chronic moniliasis with gastro-intestinal lesions roughly comparable to those found in man. The development of the lesions, however, was rarely noted except in animals fed on a diet partially deficient in vitamins, especially the antiscorbutic vitamins. This favors the view that a deficient diet, or diminished resistance such as is common following long residence in the tropics, associated frequently with gastro-intestinal infections such as amebic dysentery, are contributory factors in its production. Mycologic studies on twenty-one strains of monilia obtained from Manila and from cases in Boston invalidated home are in accord with the tentative classification into three subtypes—A, B, and C—as suggested by Boyd and Han-nibal.

Calmness of mind is one of the beautiful jewels of wisdom. It is the result of long and patient effort in self-control.—James Allen.

Medical Publicity and the Press—"There is a feeling in Brooklyn," according to the Long Island Medical Journal, "that only good can come from an understanding between the medical profession and the press. The growing power of the daily newspaper as an educational force cannot be overlooked; nor can the medical profession brush aside its responsibility for watchfulness over the public health. Organized medicine is anxious to do its part. Much harm may be done by the publication in good faith of news which soon proves to be the idlest gossip. People are deluded often, and sometimes stampeded into the arms of skillful advertisers who are careful not to pay advertising rates. Much harm may be done. The press is as anxious to be accurate as we are, but they do want news. That is what they sell, their stock in trade, the material on their shelves. We must recognize that."

DISEASES *of the* DIGESTIVE ORGANS

with Special Reference to Diagnosis and Treatment

By CHARLES D. AARON, Sc.D., M.D.

*Professor of Gastro-enterology and Dietetics, Detroit College of Medicine and Surgery;
Consulting Gastro-enterologist to Harper Hospital*

The majority of the practitioner's cases come to him because of some gastro-intestinal complaint. Dr. Aaron, a nationally known specialist, has produced a book which, for actual and practical help in treating such cases, has never been surpassed. Everything that will help you treat these patients is here in this book—the only work that deals with the *entire* digestive tract, from the mouth to the anus.

Sections of this work are complete monographs in themselves. For instance, those on Examination of the Stomach Contents, Duodenal Contents, and the Feces give you every method of value, including the use of the Stomach and Duodenal Tubes, gastric analysis, reactions of duodenal enzymes, test for occult blood in the feces, etc. Furthermore, many colored plates show you exactly how to read and interpret the various tests. With this book at hand you can handle all of these cases yourself.

Treatment of Intestinal Diseases through the Rectum is

thoroughly covered—a full Dietary is given for each condition—medication (with many prescriptions) and special measures of treatment are exhaustively treated. Diseases of the Stomach and Intestine; Neuroses; Diseases of the Liver, Bile Ducts, Gall-Bladder and Pancreas; Chronic Diarrhea; Ulcers; Toxemia; Stasis; Constipation; Appendicitis; Parasites; Hemorrhoids; etc.—all of these are dealt with in detail but without verbosity. You will find this book far above the average for definite, everyday value. It is practically an up-to-date encyclopedia on digestive diseases.

New (3d) Edition, Octavo, 904 Pages, with 164 Engravings, 48 Roentgenograms and 13 Colored Plates.
Cloth, \$10.00, net.

When Sugar is Taboo

In cases where non-sugar diets are essential, Nutradiet canned fruits may be prescribed.

They are highest quality fruits — well-known S & W quality—packed without syrup. Sterile water or the natural fruit juice is used instead.

Hence Nutradiet fruits contain less sugar than the fresh fruit itself—a minimum of carbohydrates.—for a portion of the natural sugar is thrown off in the water, after the fruit is canned.

Write for chemical analyses. Also list of grocers selling Nutradiet fruits.

[Nutradiet salt-free vegetables include a variety of vegetables packed without salt or sugar.]

Your Advertisers Deserve Your Patronage

This Journal makes every effort to exclude unworthy advertisements in order to protect its readers. The Journal could be filled with advertisements of the Nostrum class and it would prosper financially; but, since it is published primarily for the benefit of its readers and not for profit, all advertisements, known to be dishonest, or even questionable, are excluded.

Since this policy of discrimination protects you, it should be a privilege to patronize the advertisers in your own Journal. Don't experiment! Buy trustworthy goods from reliable houses.

*You may
depend on the advertisements printed in this journal*

How precious above all other things is health! When another is in sickness, let it teach us how valuable a treasure health is, which we ought to keep and preserve with all possible care. Neither will it be amiss for every man to look into his own diet. If, therefore, we have been eating, drinking, laboring, or doing anything to excess, and our bodies give us no suspicion or hint of a distemper, yet ought we nevertheless to stand upon our guard and take care of ourselves.—Plutarch's Rules of Health.

Pluriglandular Products of Harrower—In 1919, the Council on Pharmacy and Chemistry examined a number of the products of the firm of Henry R. Harrower, Glendale, California. It found none acceptable for New and Non-official Remedies. An examination of the "literature" sent out by the firm during the last year shows that its business is still largely in complex mixtures such as those reported on adversely by the Council.—Journal A. M. A.

Meroxyl—A mixture containing approximately 50 per cent of the sodium salt of 2, 4-dihydroxy-3, 5-dihydroxymercuribenzenophenone-2'-sulphonic acid, with foreign matter containing ammonium 2, 4-dihydroxybenzenophenone-2-sulphonate, sodium acetate and water. Meroxyl is a local antiseptic and germicide proposed for use in superficial infections. It is used for wet dressings of wounds, and also for irrigation of wounds and infected bladders. Meroxyl is marketed in the form of tablets containing 0.15 gm. Hynson, Westcott & Dunning, Baltimore.—Journal A. M. A.

On July 1, 1924, there were on the accredited list *sixty-two schools* of nursing, according to Anna C. Jamme, director State Bureau, with a total attendance of 2363 students, an increase of 218 over July 1, 1922.

The Gilchrist Chlorine Ejector

Sold only to reputable physicians or on their order

Announcing Improved Types

SINCE placing the original Gilchrist Chlorine Ejector on the market we have, through our dealing with a great many physicians, learned their requirements, and experience has taught us what is demanded in the use of chlorine gas for use as a therapeutic agent. These are outlined as follows:

First—An absolutely safe and trouble proof apparatus.

Second—Simplicity of adjustment and use.

Third—An apparatus that permits of treating several patients in a chamber or home and also another type with which an individual treatment can be given—both to be portable.

Fourth—Economy of use.

Fifth—Low cost and long life.

1. The personnel of the National Research Laboratories has had long experience with chlorine gas, and while the dangers connected therewith have been greatly magnified there can be unpleasant circumstances connected with its application that are guarded against in the Gilchrist Chlorine Ejector. *It is not necessary to have a cylinder of gas in the presence of the patient.*

2. We have stripped the apparatus of all unnecessary appurtenances, insuring a minimum of effort in its use and the least possible adjustment.

3. The physician will be called upon to use one type for treatment in a chamber or home when the individual type would not be suitable, for instance in

treating very small children. *Many physicians due to lack of space cannot have a chamber connected with their offices.* Therefore we have developed and placed on the market the Individual Type.

4. There are features connected with either type that permit of its use anywhere, and the greater quantity of pure chlorine gas in our cylinders insures a very low upkeep cost to the physician.

5. *The initial cost of the Gilchrist Chlorine Ejector is positively the lowest obtainable.* Simplicity of construction means low manufacturing cost. Still there has been no skimping that would detract from its efficiency, safety or appearance.

The Gilchrist method of chlorine treatment and the Gilchrist Chlorine Ejector were devised by Lt. Col. Harry L. Gilchrist of the Medical Corps of the U. S. Army.

Individual Type \$20

With Two Cylinders \$50

Both Types with Two Cylinders \$75

Individual Type Chlorine Ejector is made of crystal glass and polished hard rubber with *no metal parts to corrode*. Attached is the inhaler made of non-corrosive parts. The carrying case is of mahogany finished wood.

THE Individual Type of Gilchrist Chlorine Ejector designed especially for physicians who find it impractical to install a chlorine chamber in their offices and also for the additional advantage enabling them to furnish to their patient an ejector that may be taken to the home or office.

The simplicity of this device will appeal to the medical profession, as the physician or his assistant can charge a dozen of these individual types in fifteen minutes and have them ready for service.

This type is operated on the same principle as the other Gilchrist Ejectors. Only 50 c.c. are needed for the hour treatment, being injected into the device direct from a cylinder of pure chlorine, the cylinder then being laid aside for future use.

With the outlet apparatus adjusted (suspended about the neck, and resting just below the nose of patient) the patient opens the control valve, thus permitting the gas to seep out over the period of one hour and the gas mixing with the air gives just the concentration required.

When filled this type can be carried to the home or office by the patient without any loss of gas, or the slightest danger. No complicated adjustment is required by the patient and it is absolutely safe.

Write for our book on "The History of Chlorine Gas as a Therapeutic Agent in Certain Respiratory Diseases", for it will be an interesting and valuable adjunct to your medical library. It contains graphs and charts of results obtained covering over 900 cases treated by the Gilchrist Method.

Sold by leading Physicians, Supply Houses or direct by

SAFE
TROUBLE PROOF
SIMPLE
EFFICIENT
ECONOMICAL
PORTABLE

Improved Chamber Type \$25

With Two Cylinders \$55

Both Types with Two Cylinders \$75

The improved chamber type made of crystal glass and polished hard rubber with *no metal parts to corrode*. The carrying case is of mahogany finished wood with compartments for two cylinders.

THIS type is for use in a physician's gas chamber, the hospital, or it may be transported to a home and a treatment given there, when the individual type is not suitable, (such as in the treatment of small children for whooping cough.)

The physician or his assistant can easily turn into this ejector 600 cubic centimeters of pure chlorine gas, tighten a valve and the ejector is ready for use or transportation.

Upon entering the chlorine chamber or room in the home, the desired initial concentration is turned on, depending upon the cubical contents of the room.

Now by a simple adjustment the device is set to allow, for instance a seepage of 400 c.c. during one hour which automatically maintains the required concentration, to take care of absorption of gas by the patients or furnishings of the room.

A chart accompanying the ejector gives required initial concentration for any sized room and required amount of seepage.

The chamber ejector has a capacity sufficient for the largest room likely to be used. Lesser amounts of gas can be employed as the occasion requires.

With this type it is not necessary to take a cylinder of the gas into the home or chamber. It has no complicated mechanism; is simple, safe and durable.

SPECIAL ARTICLE

BLOOD AND TISSUE CHANGES IN ANAPHYLACTOID REACTIONS *

By P. J. HANZLIK, M. D.

(From the Department of Pharmacology, School of Medicine, Stanford University, San Francisco.)

WE ALL RECOGNIZE THE GREAT IMPORTANCE OF SANITY IN PHARMACOLOGY AND, CONSEQUENTLY, IN A MAJOR PHASE OF THERAPEUTICS. THE WAVE OF THERAPEUTIC NIHILISM THAT HAS DONE AS MUCH HARM AS DID THE POLYPHARMACY WHICH STIMULATED THE VIOLENT SWING OF THE PENDULUM OF MEDICAL OPINION IS AT AN END. THERAPEUTICS, BASED UPON A SOUND PHARMACOLOGY AND TINCTURED WITH A WISE PERSONALITY, IS THE BACKGROUND OF OUR MODERN OPINIONS AND PRACTICES.

PROFESSOR HANZLIK, AS AN INVESTIGATOR AND TEACHER AND AS CONSULTANT TO THE IMPORTANT COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION, TELLS US AN IMPORTANT AND AUTHORITATIVE STORY OF ONE PHASE OF THIS SUBJECT IN THIS ARTICLE.

PROFESSOR HANZLIK ALSO WRITES A SCIENTIFIC EDITORIAL ON SOME PHARMACOLOGIC AND THERAPEUTIC SUBJECT IN EACH ISSUE OF CALIFORNIA AND WESTERN MEDICINE. I WANT TO MAKE PUBLIC ACKNOWLEDGMENT OF HIS SUSTAINED CO-OPERATION.

PROFESSOR HANZLIK, ALTHOUGH ALSO DOCTOR OF MEDICINE, DOES NOT PRACTICE MEDICINE. BUT HE IS ALWAYS DELIGHTED TO BE OF ASSISTANCE TO ANY PHYSICIAN ABOUT PROBLEMS IN HIS SPECIAL FIELD.—EDITOR.

ANAPHYLACTOID reactions which are elicitable by a variety of agents chemically and physically different, are accompanied by definite histological, physical, and chemical changes in the blood and tissues.

These consist of congestion, hemorrhages, embolism and thrombosis in certain viscera, chiefly in the lungs; peribronchial edema; perivascular edemas, occurring chiefly around the small vessels and capillaries. In the blood there are darkening, rapid sedimentation of corpuscles, frequently hemolysis, agglutination, and disintegration of corpuscles and agglutination and increased number of platelets, flocculation and aggregation of plasma, tendency toward acidity, diminution in carbon dioxide and alkali reserve, increase in ammonia and lactic acid after some agents; changes in blood volume, due to altered vascular permeability, blood dilution, etc. There are also changes in blood pressure, heart and respiratory rates and body temperature, ranging from moderate to severe, and often resulting in varying degrees of circulatory depression and collapse.

All of these changes put together indicate disturbances in important physical and chemical mechanisms of the blood and tissues, and are believed to be fundamentally responsible for widespread alterations in cellular activity, and hence for the symptoms and reactions.

The results indicate something of the nature and limitations of non-specific therapy and the dangers of intravenous medication.

THE highly cultivated field of allergy rarely suffers for lack of interest. In this respect, it is a keen competitor of the endocrine glands and vitamins. Without being desirous of just promoting an idea about allergy, I venture to present a brief summary of studies pertaining to one of its branches, namely, the anaphylactoid reactions. This will serve to illustrate what I believe is the trend of modern thought in this subject, a line of thought that is receiving wider application in the medical sciences. Certain unsuspected and practical deductions may be made from these studies, and they should, therefore, be of interest to physicians. Before discussing these, it will serve the purpose better and make the subject plainer, if a brief resumé of the development of our knowledge of anaphylaxis is first presented.

I. DEVELOPMENT OF ANAPHYLAXIS

This may be thought of in three general stages.

Recognition of the Phenomenon—In 1839, Magendie, the noted toxicologist and predecessor of Claude Bernard, reported that the first injection of egg-white was not toxic to rabbits, but that the animals would not tolerate the same dose several days later. In 1894, S. Flexner observed the same phenomena in rabbits treated with dog serum. The phenomenon of hypersensitivity to a poison was indicated, though not recognized as such, being regarded by some as a paradoxical reaction, in the tuberculin experiments of Koch in 1890; in studies with diphtheria toxin by von Behring in 1893; in the repeated toxic injections of serum in man of Arloing and Courmont in 1894; in the toxicity of eel serum for dogs of Hericourt and Richet in 1898; in the toxic injections of tuberculin effusions in guinea pigs of Courmont in 1900 and in the hypersensitivity reinjections of cocaine of Adduco in 1894, though this latter work has never been confirmed. In his "L'Anaphylaxie" (1923), Richet tells us that it was the late Prince Albert of Monaco and G. Richard, who, in 1902, advised Richet and Portier

* Address before the Southern California Medical Association, November 14, 1924, Los Angeles.

to study the toxic properties of physalis. On returning to France, Richet was unable to procure sufficient physalis, and therefore decided to study the tentacles of actinia or sea-anemones, extracts of which were found to be very poisonous for dogs. Exceedingly small quantities were not toxic, but later injections of the same or smaller doses produced marked symptoms and death; in other words, a condition of hypersensitivity and the opposite of immunity. Richet coined the word "anaphylaxis" as against "prophylaxis," which he tried to, but could not, produce. Richet's studies stand out as recognizing for the first time the dependence of a hypersensitive state on a preceding injection of a protein substance and an incubation period of a number of days between injections in order that the sensitive state may develop. At this time, however, the fundamental importance of the phenomenon for biology was not yet appreciated. This came later.

Causal Factors and Hypotheses—Numerous authors extended the application of the principle of sensitization reaction to a variety of proteins and other agents; and advanced explanations based more or less on objective evidence, but unfortunately the evidence was too frequently confined to symptoms. The mechanism of the shock reaction was ascribed to some hypothetical substance as being specifically elaborated and fundamentally responsible. Among such substances were "apotoxin," "serotoxin," "sensibilisin," "anaphylatoxin," ferment action, disturbed ferment-antiferment balance, histamine, peptone, etc. It would not be profitable to discuss these, but it will suffice to state that not a single one of these substances has ever been demonstrated in, or isolated from, anaphylactic tissue. However, Bordet's famous experiment with "toxified agar," which was misinterpreted as a demonstration of the hypothetical "anaphylatoxin," led up gradually to a conception which is broader in scope than specificity and has nothing to do with hypothetical substances. This brings us to

The Anaphylactoid Reaction—This term is synonymous with idiosyncrasy, reaction, crisis, etc. By the anaphylactoid reaction is meant a symptomatic reaction to a substance without previous sensitization or injection, the symptoms and many other changes being practically indistinguishable from those of anaphylactic shock. Among various agents, chemically and physically unrelated, causing such reactions are agar, starch, arsphenamine, histamine, kaolin, serums, vaccines, peptone, organ extracts, metallic salts, etc. In patients, hypersusceptibility to antipyrin, iodoform, acetylsalicylic acid, orris root, and certain dyes is well known. Proteins are not necessary, and the best responses are obtained on intravenous injection, which is also true of anaphylactic shock. These reactions have been studied especially by Loewit, Milian, Stokes, Nolf, P. Schmidt, Abderhalden, Lumière, Kopaczewski, Widai, Novy, and others. Novy showed that injections of trypanosomes and dead bacilli give similar reactions. One of the most striking effects is seen with "toxified agar," first demonstrated by Bordet. (Bordet's experiment is carried out as follows: Four or five parts of serum of the same untreated, or another, guinea pig are incubated at 38 degrees C. with one part

of 0.5 per cent melted agar for two hours. The mixture is then centrifugalized and this removes most of the agar, leaving a clear supernatant fluid which is removed and incubated at 38 degrees C. for fifteen minutes. Three to five cubic centimeters of this fluid are then injected intravenously into a 300 gm. guinea pig. In from three to five minutes marked symptoms, indistinguishable from those of anaphylactic shock, develop and death may occur. At autopsy, the lungs are found distended, congested and hemorrhagic, and histologically they show emboli and thrombi composed of agglutinated erythrocytes, platelets and fibrin.) Practically the same changes were found by Karsner and myself with forty odd different agents injected in several hundred guinea pigs, by De Eds in pigeons and by De Eds, Tainter and myself in dogs. Typical results will be illustrated presently.

In this connection it is interesting to note that V. Behring ascribed the cause of the symptoms of anaphylactic shock to platelet agglutination in cerebral vessels, liver, etc. Richet speaks of anaphylaxis in vitro, which really means the formation of precipitin, or the occurrence of precipitation when antibody (serum of sensitized animal) and antigen are mixed in vitro, and on injection the precipitate causes immediate and typical symptoms of shock. Changes in physical constants (viscosity, surface tension, refraction, hydrogen-ion concentration, coagulation) of serum in anaphylactic shock and after agar-serum have been demonstrated by Zunz of Brussels. What does all this suggest? According to Widai, there is a hemoclasia, or colloidoclasia; that is, a disruption of the blood elements, its colloids, etc., as the mechanism of both the anaphylactic and anaphylactoid reactions. In fact, many authors have come ultimately to some physical-chemical conception of the nature of these reactions, and there is more to be said for this than for the elaboration of toxins, or specific substances. We should look for something more tangible and definite than such hypothetical substances as have been proposed, and obtain, if possible, a clear demonstration of the objective changes. Therefore, before going further, I wish to invite your attention to some blood and tissue changes that have been demonstrated in different species.

II. BLOOD AND TISSUE CHANGES

Our object at first was to observe and describe fully the effects of a variety of agents which were alleged to cause reactions indistinguishable from those of anaphylactic shock. As stated previously, the reports of many observers dealt merely with symptoms. We took note of these and also made histologic sections of organs, determined whether there was muscular hyperexcitability, attempted analysis by means of pharmacological agents, tried preventive measures, and studied changes in vitro. It was found that the phenomena could be produced by a variety of agents unrelated physically and chemically and that suggested the nature of the mechanism. Finally we have made chemical analyses of blood and observations of physical changes in various ways. The work has been done on several different species, namely, on guinea pigs, dogs, cats, and pigeons. Enough has been done to give

a fairly good idea of the changes. A part of the work I am presenting here has not been previously published. A good part of the work has been done in collaboration with Professor Karsner of the Western Reserve University and during the past three years with Doctors De Eds and Tainter and other workers in the Stanford laboratory. (At this point a brief description of methods used was given and twenty lantern slides were demonstrated, illustrating the results with intravenous and intraperitoneal injections, perfusion experiments, excised organs, agglutination, prevention with epinephrine and atropine; chemical analysis of blood for hemoglobin, carbon dioxide and alkali reserve, hydrogen-ion concentration, lactic acid, ammonia, urea; changes in erythrocyte and platelet counts and conditions of pigeon's blood in vivo and in vitro; darkening, hemolysis and agglutination of dog's blood by a color photograph; blood pressure and respiratory changes, etc., after such agents as agar, arsphenamine, copper sulphate, histamine, peptone, chloroform plasma, hypertonic solutions, Tyrode solution, and in anaphylaxis.) Many of the details have been previously published; others will appear in papers soon to be published. Certain changes produced by arsphenamine, phosphate and hypertonic solutions have been confirmed by Jean Oliver, Denis and V. Meysenburg, and others. The recent studies of Dale and Kellaway show that, after injection of agar-treated serum, there is an increase in the number and agglutination of platelets followed by disappearance of them, the effects being explained by an action on the blood such as would occur from its sudden exposure to an extensive and mildly injurious foreign surface.

III. EXPLANATION OF, AND DEDUCTIONS FROM, THE RESULTS

The fundamental cause, or basis, of the anaphylactoid reactions is suggested from the emboli, thrombi, precipitates, agglutination or aggregation, and disintegration of erythrocytes, agglutination and increase in thrombocytes, hemolysis, etc. All of these changes indicate disturbances in cell surfaces. The alterations in chemical composition and in appearance of the blood (blood dilution, increase in hydrogen-ion concentration, reduced carbon dioxide, reduced hemoglobin, increase in lactic acid, and darkening, agglutination, increased sedimentation and hemolysis of blood, etc.) indicate disturbances in important physical and chemical mechanisms of the blood and tissues. The perivascular and peribronchial edemas indicate alterations in capillary and cellular permeability. As a result of all these changes there are alterations in equilibrium of ions, in differences of electrical potential, in surface tension, in osmotic pressure, in viscosity and in imbibition, and probably other changes in the cells. I have already stated that changes in physical constants have been demonstrated by Zunz in serum of animals shocked with agar serum. The net result of these changes is stimulation and depression, or, in other words, the mediation of functional changes in cells, recognized in part as symptoms, reactions, etc. There is nothing unexpected about this. In fact, such physical-chemical changes and alterations in cellular functions would be expected. This is due

to the universal phenomenon of adsorption, resulting from the contact of substances with surfaces; in our case, of course, with surfaces of corpuscles, endothelium of blood vessels, plasma proteins and cells of the tissues. By adsorption is meant the well-known tendency of substances to accumulate at or on surfaces. As a result of this accumulation, energy is expended at the interface where the substance is in contact with the surface, and from this is derived a change in surface tension. Sometimes surface tension is defined as the tendency to the exposure of the smallest surface possible. The working of this force is nicely illustrated by the formation of rain water into droplets, oil into globules in an emulsion, the darting of a camphor granule on water, etc. Furthermore, it is well known that, by changing the surface tension, the contour or shape of objects can be altered. This is conveniently accomplished by the addition of salts, acids, etc., which increase the surface tension, and by bile, soap and most organic substances which lower it. In our case the change toward acidity and the disturbance in salt (ionic) balance would tend to operate in the same direction. By judicious selection of agents which lower and increase the surface tension it is possible to produce amoeboid motion in inanimate objects; for example, in oil droplets. In other words, contraction and relaxation, indicating changes in functional activity, and simulating stimulation and depression to a degree, can be produced by the intervention of physical forces alone.

Such phenomena illustrate the operation of and changes in only one kind of physical force. There are changes in many other forces, all probably going on at the same time. Hence, it is reasonable to expect changes in or modifications of cellular activity, the multiplicity of factors involved in the tissues being conducive, if anything, toward a complexity of symptoms and other changes. It has been suggested that the physical and chemical changes which have been described are the consequence, and not the cause, of anaphylactoid reactions. This is the view of Lumière, who nevertheless regards the flocculations, aggregations and agglutinations as fundamental physical changes which bring about the physiological. It is obvious that agglutination, flocculation, precipitin formation, etc., are tantamount to saying surface changes, involving physical and chemical changes. Hence, it appears to me that the basis of the anaphylactoid reactions is a disturbance in the physical-chemical mechanisms of the blood and tissues.

Nature and Limitations of Non-specific Therapy—Many agents causing anaphylactoid reactions are used as non-specific agents in the treatment of disease, especially of that with indefinite or unknown etiology, the aim being to induce such reactions for the sake of producing beneficial therapeutic effects, if not cure. The effects appear to be brought about through widespread alterations in cellular activity. However, sometimes the reactions are alarming and even result in death. These changes would be expected from the embolism, thrombosis, agglutination and flocculation, which occur in the blood stream and in important organs. Hence, such agents should be used cautiously.

Dangers of Intravenous Medication—The same holds true with respect to the indiscriminate use of agents and drugs intravenously. From what has been said, it follows that physical and chemical changes in the blood and tissues may always be expected under these conditions. Dangerous results may occur with relatively inert and inactive agents; for example, with agar, acacia, starch and kaolin. In fact, the results cannot be predicted from the physical and chemical properties of the agents. Again, an agent may be beneficial to one function and detrimental to others. Intravenous therapy is chiefly a fad promoted largely by unscrupulous manufacturers, and, unfortunately, also by some physicians who fail to realize the dangers involved, and to appreciate that most drugs so advocated are promptly and readily absorbed when given by mouth, hypodermically or intramuscularly. There is no excuse for administering distilled water, hexamethyleneamine, iodide and salicylate intravenously, because all of their ordinary effects are promptly and readily obtained when they are given by mouth. On the contrary, detrimental and undesirable effects may occur when they are administered intravenously. Recently, when a genito-urinary surgeon was asked to explain the urinary antiseptic superiority of hexamethyleneamine intravenously, which he advocated in preference to its oral administration, he replied by saying that he was told it was so. Unfortunately, hearsay evidence is not convincing. There are only two drugs for which, at present, the intravenous route is indicated to secure their therapeutic effects, and these are arsphenamine and strophanthine. But, even these two agents are being replaced by combinations with other drugs and by substitutes, in order that their effects may be secured intramuscularly and subcutaneously so as to avoid detrimental effects from intravenous injection. Such dyes as rose bengal, phenoltetrachlorophthalein and others, which are being exploited as diagnostic agents and injected intravenously, are not harmless. We have had considerable experience recently with these dyes in dogs, rabbits, guinea pigs, and pigeons. They cause hemolysis, impart a brown color to the plasma and even produce systemic symptoms, not to mention the local effects in veins (phlebitis). We have had no experience with mercurochrome, but scarcely a month passes without a call from a physician drawing our attention to the marked systemic reactions from this agent, and recent reports in the literature testify adequately to the occurrence of undesirable and harmful effects when it is used intravenously.

IV. CONCLUSIONS

1. Anaphylactoid reactions, which are elicitable by a variety of agents chemically and physically different, are accompanied by definite histological, physical and chemical changes in the blood and tissues.
2. These consist of congestion, hemorrhages, embolism and thrombosis in certain viscera, chiefly in the lungs; peribronchial edema; perivascular edemas, occurring chiefly around the small vessels and capillaries. In the blood there are darkening, rapid sedimentation of corpuscles, frequently hemolysis, agglutination, and disintegration of corpuscles and agglutination and increased number of platelets, flocculation and aggregation of plasma, tendency

toward acidity, diminution in carbon dioxide and alkali reserve, increase in ammonia and lactic acid after some agents; changes in blood volume, due to altered vascular permeability, blood dilution, etc. There are also changes in blood pressure, heart and respiratory rates and body temperature, ranging from moderate to severe, and often resulting in varying degrees of circulatory depression and collapse.

3. All of these changes put together indicate disturbances in important physical and chemical mechanisms of the blood and tissues, and are believed to be fundamentally responsible for widespread alterations in cellular activity, and hence for the symptoms and reactions.

4. The results indicate something of the nature and limitations of non-specific therapy and the dangers of intravenous medication.

Stanford Medical School.

REASONS FOR A CHILD GUIDANCE CLINIC

By ROBERT LEWIS RICHARDS, M. D., *San Francisco*

This neglected problem is truly a medical problem in its widest service, as well as scientific sense, but it is not a medical education problem as medical clinics basically are, and it has relationship to schools, courts, and social agencies, which are more than the accepted medical facts.

MEDICINE began in the dim past as a form of health service to man. Medicine remains in high esteem when she continues this function. People are not so much interested in medicine's scientific erudition as in what benefit medicine is to them individually. Research of itself is valued and praised when it is of medical service to people. We are presenting today not only a field of service where there is great opportunity for the growing formative stage of human behavior, but also among those in whom people are most interested, viz.—the young; the adolescent.

University clinic meetings are noted for their scientific interest and lack of positive conclusions along treatment lines. Practicing doctors' hospital meetings are noted for their stress upon diagnosis and the effect of treatment upon the individual. In child guidance clinics, we have not only the study of stages of mental as well as physical growth with all its trends and determining factors, but also the results in the individual child in its relation to the family, to the school, to the courts, and to the various social agencies. It is medicine in its broadest, most appreciated aspects.

Unsettled post-war families are finding themselves inadequate for the child problems of the present day. The schools estimate a cost of \$4,000,000 for back-graded scholars in California for the biennium, in spite of physical examinations, dental examinations, and a school program far in excess of the supposedly essential needs of a few years ago. The juvenile courts are crowded, and the institutions for delinquents are admittedly inadequate. The worst crimes are committed by those under 24 years, and are increasing in numbers. The many organizations for those financially dependent have grown until we have organized community chests of large proportions, and even call for state and federal aid in addition.

More specifically, detailed surveys have been made of schools, courts, and dependants in six large cities, in several smaller cities, and in rural communities. There is striking unanimity in the findings. From back-graded, misfitted pupils in the grammar grades come later the juvenile delinquents, and later still the violent criminals or the chronically dependent. There are abundant evidences of at least partially remediable mental growth deformities. While physical defects, economic handicaps, lack of sympathy, and lack of sufficient intelligence are found, the paramount difficulty is found in the qualitative mental side, and has to do with the mental growth and behavior problems. The problem is twice as big as the mentally defective alone. Indeed the moron properly placed is a happy, effective member of the community. The problems remain after you have remedied all the physical ills and have increased all the weights, and given proper ventilation, light, and play to all the children. The teachers may be well paid and sympathetic, the judges without legal restraint, and abundant funds for all dependency organizations; and you still have your problem largely unsolved. All this is known from experience.

The mental hygiene value in preventing the socially disturbing psychoses and psychoneuroses is so evident that all organizations and institutions having to do with mental conditions are vitally interested in child guidance work. State hospitals alone cost California in round numbers about \$10,000,000 per biennium, and that is a tax directly or indirectly of \$1.50 per inhabitant per year. If you add to this the cost in schools, courts, and dependency organizations, you have doubled and trebled this amount. If to this financial loss you add the cost in family life and the loss in good citizenship, you have a staggering loss, demanding consideration and action by the California Medical Association.

Since the beginning of the problem of the best child development is, of course, the selection of the proper parents for the children, the lessons of a child guidance clinic will do more to secure this than any number of idealistic talks on eugenics. But the element of chance in heredity is not removed by Mendel's laws, and you cannot definitely foretell a child from a knowledge of the parents. You can learn its possible trends for good and bad; its probable strength and its probable weaknesses. Heredity is a vague chart of an unknown country, the undeveloped negative, the seed for planting—but results depend upon remembering the general landmarks, developing the negative properly, and growing the plant in the appropriate conditions. In the present day of individual indulgence and halting group action, we can expect only an academic interest in the principles of eugenics and child guidance work is more needed now than it may be later. Also I am heartily in sympathy with "self-expression" and "children's crusades" against arbitrary parental prohibitions, but guidance is necessary, and in practical experience, the child guidance clinic is most appreciated by the child itself. It was not established to support authority, but to see that children may have every chance to grow, to develop, to have their rights as far as their origin or heredity will permit, and also while they are not fixed, but

formative. Child guidance searches the hereditary factors as no other effort does. It is not content with the history of disease incidence, but goes on to the behavior records, the personality trends, and the mental capacity and quality of the child's forebears.

Besides the data of origin of the child, there is the record of growth of the child, of epochal periods successfully or unsuccessfully passed, and why, of favorable and unfavorable conditions of growth and of the developing life pattern. There is a vast difference between the stage of purely sense perception and self-interest with jealousy and fears of the first years, and the dramatization of life in the next or pre-school stage, or stage of interest in the family as well as himself. The epoch of school with passing from the family protection to a wider, more impersonal, unsympathetic group is a stress too little recognized. It is not without reason that this has been called "the prickly stage," the "urchin stage," "the big injun stage," "the stage of pirates and robbers." The schools devote four years to this period, and serious school work begins in the fifth grade. It is a period of sorting, but unfortunately not a period of especially remedying defects, favoring growth in certain directions, establishing mental habits commensurate with individual possibilities. The tendency to regard all children as alike grows largely out of the adult transferring his own mental processes to all children, and not regarding the child as a growing different individual.

With the advent of puberty, a new element of growth enters, viz: an interest or relationship to another individual of the opposite sex. This looks to the establishment of a new family group and a repetition of the human cycle. The old family must pass and the new family be established. Mentally, this is the greatest transition of all, and is difficult or easy, depending less upon the hereditary trends than the previous environment favoring or opposing normal mental growth. Experience shows that few pass this stage without deformities and scars, which seriously interfere with subsequent life growth. The characteristic tendencies show earlier than 12 to 14 years, but are usually recognized then, because of the startling physical changes, which can be seen by anybody. It is a physical maturing, but a mental infancy. It requires mental guidance as much as infancy required physical guidance, but by both father and mother, because the bisexual is now to the front. Teachers deal with too large numbers of individuals: courts with only the socially delinquent; other organizations with dependent failures; some doctors with the established failures of growth or deformities; the Church is limited in its field—none of these can take the place of father and mother. It requires a patience unbounded, a supervision unrelenting, and a confidence never obtainable by other than father and mother. It does, however, require the knowledge and co-operation in their respective fields of the schools, the courts, dependency organizations, doctors, and the Church. There is work for all, if we expect the success of group organization or democracy and mental health or fruition. It is not a single situation met and adjusted or failed in. It is a growing something that progresses, and is normal or stunted or deformed for the balance of life in a

social organization not now so much dependent upon leaders as upon co-operation of the units. It is the continuance of efforts that distinguishes this problem from the other problems of the various agencies mentioned, and leads to the conception of a child guidance. Medical clinics, courts, social agencies, etc., deal with concrete situations and adjust limited set problems. Child guidance service deals with a growth, a continued effort at mental hygiene favoring proper mental growths.

The factors of infectious diseases, malfunctioning organs, internal glands, or body chemistry, which are handled by physicians, may delay the rate of growth, but none of them attempt to determine the direction of growth, and others are only secondary factors in the problems of human behavior.

Neither does the school organization take into consideration the growth factors of the family environment or the emotional side of the child. Roughly, the school allows about four grades for growth differences, but is not equipped and cannot make the necessary search for the factors retarding mental growth. Waiting for four lost or back grades to show mentally retarded growth in the public schools is not economical or wise. We should not forget that investigations have shown that these back grades produce dependents and delinquents. Individually, it produces tragedy and despair in the pupil stamped as an inferior.

The courts and social agencies are fully occupied with the end-results. Primarily, they repress by punishment or aid temporarily by money. They are vitally interested in preventing such end-results, but their function is not treatment and prevention. A delinquent or a dependent with them is an individual for emergency management, but the treatment and prevention belongs to another co-ordinating organization. Frequently, in lunacy courts, I have, with the authority of the judge, outlined a plan of treatment promising success, but at that point we were blocked, and the continued application of the details of treatment was out of our reach. I have frequently been asked for advice by social agencies, and they have thereby acquired a better insight into the details of the problem, but they were limited in time and finances, and it was fully recognized that we were dealing with an emergency. In psychiatric medical clinics I have again performed the same functions in a diagnostic way, but the treatment end failed in continuance of application of details. The more recently established health centers have also practically been diagnostic and emergency treatment centers, but with no continuing treatment relationship. Psychopathic hospitals are valuable parts of this program, and perform a great purpose in their in-patient and out-patient services, but they cannot offer the continued effort or co-ordinate the efforts of agencies needed in the problems as a separate child guidance clinic can. The psychopathic hospital has also still the unmerited but real prejudice of mental disease to hamper it in any wider relationship at the present time.

This neglected problem is truly a medical problem in its widest service, as well as scientific sense, but it is not a medical education problem as medical

clinics basically are, and it has relationship to schools, courts, and social agencies, which are more than the accepted medical facts. Child guidance service is by no means confined to the individual patient. The patient is studied from every known angle. Where there is an equipped medical unit to determine or treat any medical angle, the patient is sent there for that medical purpose, and no new machinery is installed. In the school management every existing school agency is given the data and advice as to how that particular phase can be managed, in view of all the known accumulated facts. The court is furnished in the same way with information and advice from the mental hygiene point of view and practical experience. The family, as the special nurturing soil in which the plant grows, is studied from all angles and aided in every way to place this child so that it can best grow as God intended. Every young child is overwhelmed with the authority and power of those about it. Every adolescent is overwhelmed by his own personality, which he understands only partly, guards jealously and mistrusts as we mistrust any untried machine. Either the young child or the adolescent responds quickly and fully to an intelligent approach in which he feels that he is understood. The medical clinics will give generously and largely in this plan, but they will receive in return in many ways. The expensive problem of the repeater and the one who does not co-operate in treatment will be further solved. The medical prejudice of the present day will be much broken down by the wider contact and practical service. The popular trial and error method of trying now this treatment out, and now that treatment, will disappear through the methods of such practical service as the child guidance clinic. Medicine will advance into a new field of preventive medicine comparable with asepsis, immunology, and various existing public health measures, not by a spectacular laboratory discovery, but by an extension into the field of mental hygiene. It will be a co-operative group including the family, the schools, the church, the courts, the social agencies, as well as medicine, and the group will stand together. At the same time this work will be under medical guidance and initiated by medicine. This is not socialized medicine, but medical leadership in the mental field which medicine has long neglected too much. Inasfar as medicine has always been social as well as scientific and altruistic, the child guidance clinic will also be social under medical guidance. What psychiatric problem can be solved in the clinic will be solved there, but no new machinery will be installed. Each existing agency will receive the same rewards it now receives, but there will be a co-ordinating center doing the psychiatric work not now done, and making preventive medicine operative in this stage of human life where success is most largely rewarded and failure is so woe-fully costly. There would seem to be no reason why a demonstration of these facts in Los Angeles and San Francisco should not be accepted and urged by the California Medical Association.

Scientific infant-feeding and pseudo-scientific feeding are not synonymous; but some people make themselves believe so.—Nebraska Medical Journal.

LOS ANGELES' EXPERIENCE IN CHILD GUIDANCE WORK

By AARON J. ROSANOFF, M. D., *Los Angeles*

The aim of the child guidance clinic is preventive work along the lines of mental hygiene.

It is obviously difficult, if not impossible, to demonstrate fully the effectiveness of such work.

It has been estimated that during the first year of its work the child guidance clinic can handle about five hundred cases.

The clinic procedure contains nothing that is new in mental science, except perhaps as it involves a more complete organization for the carrying out of all that we know has to be done.

IN MAY, 1923, Miss Mildred C. Scoville, a representative of The National Committee for Mental Hygiene, came to Los Angeles in order to consult with persons in this city who are interested in mental hygiene, concerning the feasibility of introducing child guidance work here.

She brought information to the effect that the Commonwealth Fund had placed at the disposal of The National Committee for Mental Hygiene financial means for the purpose of organizing demonstration child guidance clinics in various cities in the United States. Twenty-five cities, besides Los Angeles, had already been negotiating for the purpose of securing such a demonstration clinic. All requests for such demonstrations could not be granted, and it was understood that only a small number of cities would be selected on the basis of possessing the most highly developed social agencies, which would work in co-operation with the demonstration clinic.

One of the requirements of The National Committee for Mental Hygiene was that local authorities undertake to organize and finance, to the extent of a minimum annual budget of \$25,000, a permanent child guidance clinic to be maintained along the lines of the demonstration clinic. In the event of this city being chosen to receive the demonstration clinic, the latter would operate here for one year.

Great interest in this project was aroused in this community, and, when a few months later Dr. V. V. Anderson of The National Committee paid a visit to this city, in order to investigate the local situation and to proceed further with negotiations, a new organization was created, the name of which was Mental Hygiene Organization of Los Angeles County.

I need not enter here upon the discussion of the full scope of activities which this organization has planned. It was understood that during the first year of its existence it would concentrate its efforts almost exclusively on the problem of securing for this city a demonstration clinic, to be financed for one year by the Commonwealth Fund, and to be conducted under the auspices of The National Committee for Mental Hygiene.

The organization succeeded in attracting a number of prominent and influential persons in this community and securing quarters for the demonstration clinic in the Anita M. Baldwin Hospital for Babies, with the addition of an adjoining building and part of another building also adjoining, on the grounds of the California Lutheran Hospital. The local

mental hygiene organization succeeded in securing not only funds for meeting its own expenses, but also pledges for funds necessary to maintain a permanent child guidance clinic, according to the requirements of The National Committee for Mental Hygiene.

The work of this organization resulted in Los Angeles being chosen from among twenty-six cities in the United States as the location for the demonstration clinic, which was then available. The clinic staff arrived, preliminary organization work was quickly accomplished, the quarters were prepared, and the new clinic was formally opened for the reception of patients on February 12, 1924.

The plans of the Commonwealth Fund involved the expenditure of between fifty and sixty thousand dollars during the year of demonstration. The demonstration clinic staff consists of a director, chief of staff, two psychologists, a chief of social service, six psychiatric social workers, a clinic manager, a statistician, and stenographers.

A local volunteer staff was then secured for work in connection with the child guidance clinic, the time given for such work by each member of the volunteer staff varying from one-half a day per week to full time. The volunteer staff consists of between thirty and forty members, including neuropsychiatrists, physicians and surgeons representing other medical specialties, psychologists, and social workers connected with various social agencies in the community, such as the Juvenile Court, Probation Department, Bureau of Catholic Charities, Federation of Jewish Welfare Organizations, the city schools, etc.

While the work of the demonstration clinic was to consist mainly of investigation and diagnosis, that of the local social agencies was to consist mainly in referring cases to the clinic and carrying out therapeutic recommendations resulting from the investigation and diagnosis.

The aim of the child guidance clinic is preventive work along the lines of mental hygiene. The theory is that such work is feasible; that is to say, that the prevention of mental disorders and of severe social maladjustment occurring on the basis of such mental disorders can best be prevented by taking cognizance of behavior abnormalities and evidences of beginning maladjustment in childhood.

It is obviously difficult, if not impossible, to demonstrate fully the effectiveness of such work. In a given case it may be judged, from the behavior and psychic abnormality presented by the child, that such child, if not taken in hand and properly treated, is threatened with development of grave, perhaps chronic and deteriorating, mental disorders; and it is not so difficult to show that measures of treatment in the given cases have been effective, insofar as they have removed the difficulties observed before the treatment was instituted. But it is never possible to say that, had the child been left without such attention, it might not have found a readjustment spontaneously and would surely have drifted toward the bad ending of which it was judged to be in danger. On the other hand, it can easily be shown that under conditions of the best possible management and mental hygiene measures the readjustment sought in some cases fails to materialize, and the bad

ending anticipated happens, in spite of all that is done.

The work of child guidance must and will be carried on by those who, in the absence of positive demonstration, have faith in the proposition that the problems of childhood maladjustment, and of all that it leads to later on, will not take care of themselves as well as they would be taken care of with the aid of careful and thorough investigation, diagnosis and treatment of each individual case.

It has been estimated that during the first year of its work the child guidance clinic can handle about five hundred cases. When one considers the amount of money and energy expended in order to take care of this number of cases, it will readily be thought that this work is expensive. It is true that during the demonstration year much of the work of the clinic is work of education, organization, developing a system of co-operation between the clinic and various social agencies, introducing mental hygiene functions in the operations of the social agencies themselves, and developing local machinery for the carrying out of a standard technic. It is probable that after the year's demonstration the child guidance clinic will be in a position to do its work more quickly and at lesser expense. Nevertheless, a careful selection of clinical material will always be in order.

The Child Guidance Clinic can never afford, for instance, the spending of much of its energy and time upon cases of marked mental deficiency, or upon other cases in which the problem obviously would be met only by permanent institutional custody. It is hoped merely that a too ready resort to institutional custody, which may prove detrimental rather than beneficial to a child, may be avoided in many selected cases.

In this connection it may be pointed out that social maladjustment in childhood, as well as in later life, arises on the basis of both constitutional and environmental causes. It is the opinion of many who have studied these problems that probably in no case are either the constitutional or environmental causes alone responsible for the maladjustment, but always a combination of the two. The most difficult task in any given case is to measure exactly the relative importance of each of these two groups of causes. Constitutional causes are probably not susceptible of much modification, and cases in which these causes may be judged to be of the greater relative importance are those which the clinic would not select for its most intensive work. The clinic proposes to select rather those cases in which the more modifiable environmental causes are of the greater relative importance.

It follows from what has been said that no cases can be rejected outright by the clinic. The clinic must and will undertake at least that amount of investigation of every case that is brought to it, which would suffice for a fairly reliable judgment, to the effect that the less modifiable constitutional factors are relatively of such great importance that further expenditure of time and energy on the part of the clinic would not be justified. In such a case the clinic would proceed to recommend the taking over of the case by an institution or such other social

agency which may be properly charged with its further management.

The clinic procedure contains nothing that is new in mental science, except perhaps as it involves a more complete organization for the carrying out of all that we know has to be done. A child, upon being brought to the clinic becomes the object of the following steps of investigation and treatment: 1. Social investigation, which includes history-taking and home investigation, investigation of its school record, etc. 2. Physical examination. 3. Psychological examination, which includes measurements of intelligence, educational achievement, and of special abilities and disabilities. 4. Psychiatric examination. 5. Plan of treatment, which may include medical, psychiatric, educational or social measures, or any combination of these.

It would be impossible for an individual, however expert, to carry out such a procedure. Every phase of the work requires years of specialization, and for that reason becomes a problem for a group of workers, such as a child guidance clinic is made up of.

The data that are gathered by the various members of the group, in the study of the case, are brought together and discussed at staff conferences, which are held daily; and at these conferences further investigation or special diagnostic procedures may be suggested, such as x-ray, lumbar puncture, or any other measure, for the clearing up of doubtful points. At these conferences also the treatment is outlined and decided upon.

The problem then remains of following up the case for the study of its progress and modifying the treatment from time to time, according to indications as they may arise.

The Child Guidance Clinic has now been in operation in Los Angeles three months. In the meantime the local mental hygiene organization became the Southern California Society for Mental Hygiene, because some adjoining counties in Southern California became interested in the progress of mental hygiene, have expressed a desire to participate in the movement, and in some instances have gone so far as to take steps towards the organization of child guidance clinics in their own community.

The Mental Hygiene Society has taken upon itself to provide publicity not only through the daily press and by means of public lectures, but also through the medium of a monthly publication known as the Mental Hygiene Bulletin of the Southern California Society for Mental Hygiene.

This publicity has resulted in bringing not only a sufficient number of cases to the clinic to furnish work to full capacity, but has resulted in a waiting list of patients.

A few days ago the director of the clinic kindly furnished me with a statistical statement of the work of the clinic up to date. I learn that 252 applicants have appeared at the clinic. Of these, 106 were brought by parents, 79 referred by schools, 41 by physicians and other clinics, and 26 by various social agencies.

The clinic has not been in existence a sufficient length of time to afford instances by which the results of its work might be demonstrated. However,

the director has furnished me with abstracts of two cases which will be of interest as illustrating rather common types of difficulty.

The first case is that of a girl, 7 years 9 months of age, referred to the clinic by her grandmother because of unmanageable behavior at home and temper tantrums. The maternal grandmother had suffered from a nervous breakdown. A great-aunt had had a manic-depressive psychosis, and an aunt suffered from goiter and was nervous and irritable. At home she was constantly the witness of psychotic and hypochondriacal symptoms exhibited by various members of the family, and her brother teased her and frightened her frequently. The grandfather told her ghost and other fear-inspiring stories. The great-aunt who was suffering from a manic-depressive attack was seen by the child continually weeping and complaining of various physical symptoms and even observed by her in a suicidal attempt.

When she was a mere baby of fifteen months she began to have temper tantrums, during which she would hold her breath, turn purple, and grow quite limp. These were occasioned by trifles, such as the brother taking bread and butter away from her, and they were treated by dashing cold water over her and on one occasion by holding her under the faucet. She constantly complains of headaches, stomachache, and pain in the heart. These complaints are much like those of her great-aunt and grandmother. At night she frequently has nightmares. Her imitation of the symptoms which she had observed in the grown-up people in the house has gone so far as to lead her to make suicidal threats, and her nightmares were apparently repetitions of the ghost stories which she had been told.

The treatment consisted mainly of changing the family's methods with her. A plan was outlined for the family in specific detail, and her symptoms almost completely disappeared with surprising promptness. There can be no question that immediate and direct beneficial results have been secured in this case, in which symptoms had persisted from infancy. Would she have been destined to become definitely and permanently psychoneurotic if not thus cared for? Has she now been secured against such an outcome? It is in the nature of things that these questions cannot be positively answered, but if there is anything at all in mental hygiene it would seem that the results already accomplished are unquestionably worth while.

The second case is that of a boy, aged 13 years 4 months, who was referred to the clinic because he had never been able to learn to read well, in spite of the fact that he had been rated as of superior intelligence on the basis of a mental test given him at school. Investigation revealed that he had a mental age of 15 years 9 months; that is to say, 2 years 5 months above his chronological age, while his educational age was only 11 years. In reading and spelling he had about a nine-year rating, and it was clear that his special reading disability had stood in the way of his general educational progress.

He was compelled to repeat the low second grade twice and the low third grade once, whereupon he was for five semesters in an opportunity room. At the time he was brought to the clinic he was in an

upper remedial adjustment room, but had not been making satisfactory progress there. Being intelligent and ambitious, he was keenly conscious of his difficulty and humiliated by his failures. This had apparently resulted in the development of an inferiority complex, which was heightened by an overcritical attitude on the part of his mother.

As is well known, such a disability as this boy has can be readily removed by special methods of training, which make use of motor processes. The removal of his reading disability by such a method will remove the only existing obstacle to his educational progress, and will take away all occasion for any inferiority complex. Such treatment has been recommended in his case and will, of course, take several months to carry out.

Those of us who have taken part in the mental hygiene movement in Southern California, and have had to do with the organization of the child guidance clinic here, feel encouraged with the work so far accomplished. We feel that this community cannot afford to get along without child guidance provision, and we propose to do all in our power to help establish such provision in Los Angeles on a permanent basis.

2007 Wilshire Boulevard.

How to Prepare and to Deliver a Paper to a Medical Society—In an interesting discussion of this subject, E. S. Moorhead (Canadian Medical Association Journal) emphasizes the obvious truth that: "No speech and no paper was ever spoiled by being too short, but many have suffered from prolixity. My ideal is to leave my audience with a lingering regret that I had not gone on a little longer. Prepare your papers, prepare as long a paper as you like, and then revise it. Revise it with a blue pencil, and with two mottoes before you: 'Brevity is the soul of wit,' and 'Precise knowledge puts an end to all conversation.' When you have got your paper to this stage, proceed to revise the English; see that your sentences run smoothly; if similar terms have to be used frequently, consult that most valuable aid, Roget's Thesaurus, in order that the same word may not be used time and again. You must then read your paper aloud. Do it at home. Read it until your delivery is fluent and punctuation correct. Note whether you come within the time limit or not; if you exceed the limit, cut again. Never apologize for your address, either at the beginning or at the end. To me there is nothing more offensive than to be told by the speaker that he had hurriedly prepared his paper a short while before. IF A GROUP OF INTELLIGENT AND EDUCATED MEN PAY YOU THE COMPLIMENT OF COMING TO LISTEN TO YOU, THE LEAST THAT YOU CAN DO IS TO OFFER THE VERY BEST CONSTRUCTED MATERIAL THAT IS AT YOUR COMMAND."

"The State Journal"—"The journal of a state medical association should be something more than a periodical that prints the proceedings of the state association and perhaps an occasional report of a county medical society meeting," says Albert E. Bulson Jr., editor Indiana Medical Journal (Bulletin A. M. A.). "It ought to be a live, up-to-date medical journal, with departments devoted to original articles of the best type obtainable, news and personal notes of interest to the medical men of the state, society proceedings, a monthly report from the Council on Pharmacy and Chemistry of the A. M. A., and should reflect the doings of medicine everywhere. The editorial department should be full of pep, and always in support of the highest ideals of personal and professional conduct on the part of medical men. The editor should not be afraid to speak in disparagement of duplicity or unethical conduct, or to offer constructive criticism of conditions that concern the practice of medicine."

ADULT DELINQUENCY

ITS PREVENTION BY MENTAL HYGIENE IN
CHILDHOODBy JOSEPH CATTON, M. D., *San Francisco*

The neuropsychiatrist finds that maladjustment expresses itself in tendency to suicide, unemployment, criminality, or some other form of failure.

We should not constantly spend money, time, and energy on attempting to improve those not capable of improvement.

It is the attempt of the individual to adjust himself in the wrong group or at the wrong level that brings disaster.

DISCUSSION by Josephine A. Jackson, *Pasadena*, and Adelaide Brown, *San Francisco*.

OTHER speakers are telling us, in some detail, of the technique of mental hygiene care, through child guidance clinics and children's habit clinics.

My communication is related to theirs, because mental hygiene in childhood may be a powerful weapon in the prevention of delinquency in the adult.

Society has failed largely in its handling of the criminal, the prostitute, the unemployed, and the pauper. The law has proven its failure with the criminal in a large proportion of the cases. Two-thirds to three-quarters of the inmates of state prisons are repeaters. The law has protected society temporarily by keeping the prisoner in custody: it has done some punishing. Reformation of the criminal has not succeeded at all in about 75 per cent of the cases, and we know little of the result in the other 25 per cent. How could the law have done otherwise? How could it reform, guide, or treat the criminal? First, it would have to know what sort of person it had to reform, to guide, to treat: and it has not had the machinery for obtaining this information.

Medicine may help in the problem, and here is the reason. Medicine will approach the criminal as she does the patient, and, through history and examinations, may determine physical and mental defects. Further, with special psychiatric, psychological, and sociological investigation, she will discover various maladjustments of the criminal and certain factors which appear to her to be in causal relation to the conduct disorder or crime.

The neuropsychiatrist finds that maladjustment expresses itself in tendency to suicide, unemployment, criminality, or some other form of failure. He feels that heredity taint, bad influences in infancy and childhood, poor home surroundings, lack of proper training, etc., etc., are etiological of maladjustment, and that certain forms of mental disease and defect may often be the basic causes.

One has only to glance at the literature on this subject to learn that careful surveys have been made of these relationships. There one may read of the percentages of insane, defective, and the rest, among the delinquents. But one should always ask for comparative statistics on groups of norms. In any event, one learns from Glueck that, among criminals at Sing Sing, 12 per cent are insane, 28 per cent defective, and 18 per cent psychopathic (58 per cent mentally abnormal); and from Anderson that, among the juvenile delinquents in Cincinnati, 26 per cent

were psychopathic or mentally ill, 26 per cent subnormal, 8.4 per cent feeble-minded (66 per cent psychiatric problems); from Anderson that dependents in Cincinnati were 75 per cent psychiatric problems, 25 per cent being mentally ill; from Adler that 35 per cent of unemployed were "inadequates," and all the others showed paranoid make-ups, or emotional instability. Similar statistics are available for inmates in reformatories, for prostitute groups and others. Wherever surveys are made of these various delinquent types, from 50 to 70 per cent are found to present psychiatric problems.

The controls show no such high percentages of psychopathy. The mental defective averages do not show such a great difference between the adjusted and the maladjusted. In this regard, statistics of different observers show wide variations. Terman found about 22 per cent below average in the norm. In Anderson's school-children group, only 6.8 per cent were below average. A comparison of Anderson's totals on the school children on the one hand, with the totals of his delinquency group, and other delinquent groups on the other hand, is rather convincing. Only 6 to 10 per cent of his school children are problem cases and psychiatric cases, whereas 50 to 75 per cent of adult delinquents and failures are psychiatric cases. *In other words, in a group that, as a group, is getting along, less than one in ten present mental hygiene problems. In a group that in adult life is not getting along, two or three in each four are mental hygiene problems.* And medicine cannot apply to the adult what should have been applied to the child. Mental hygiene in childhood should have reached and should have helped in some degree, at least, two to three out of each four of our various adult delinquents.

Each of us has been able to trace through the childhood of "failure cases," the lack of proper habit-forming, proper guidance, proper education; pernicious home-life; and the rest. My small experience in examination of criminals in the San Francisco jails, would indicate that most of them were mental hygiene problems in childhood.

Hereditary factors have shown themselves repeatedly. Some mental defect has been found coupled with criminality in at least one in five of our cases. We have had the feeling that, had these defects been noted early and dealt with, the man might have found some adjustment at an appropriate level. These defectives might have made very good elevator boys, chore men, ranch hands, laborers, domestics, etc. They might have been more properly placed in industry and life; have been taught the satisfaction that comes with work well done, even though it is lowly; might have been prevented from developing "white-collar" aspirations with "overall" mentalities. Fernald prepared 50 per cent of his imbeciles so that after training they made good.

Without burdening you with repetition, may I state that our investigations have shown consistently the various factors which have been unearthed in more thorough and scientifically conducted surveys. At least 20 per cent of our cases show quantitative mental defect. At least 10 per cent might be diagnosed as medically insane. Another 20 per cent would be listed as psychopathic, and still another 20

per cent show marked psychoneurotic disturbance. I would say a grand total of 70 per cent show psychiatric aspects. One hundred per cent show behavior disturbance of antisocial or asocial type. But this sort of information has been available for some time. I believe the public is "sold" on that part of our problem. What the public wants now is to learn specifically our modes of treatment. The portion of the public which handles the purse-strings wants proof in the form of results. It wants to know from the *results*, and not from the *theory*, that our plans are economically sound, practical, and worth while.

I have been asked many times, in effect: Do you do more than investigate, diagnose, classify, recommend? What, concretely, have you done in the way of treatment? What are the positive evidences of results? Are the factors you find in examination of the maladjusted different from those in the adjusted?

I can answer the last question with a definite "Yes." I do not believe that the other questions can be answered so definitely at this time.

Mental hygienists have a big problem here: this problem of preparation for adjustment. It has taken nature thousands of years unnumbered to develop in man a nervous system, and hormones, and other factors beyond our knowledge. All this evolution has been towards the adjustment of each body cell to all of the others; and each of our body organs to the others. At its best, this adjustment lasts from three to five score years, at which point nature confesses its failure in death. We certainly, therefore, may approach this problem with all of humility and little of conceit. We have the right, however, to hope that something definite may be accomplished.

I believe that we ought to take stock. We ought to load our cause with every possible bit of optimism and enthusiasm. On the other hand, we ought to allow enough of common-sense pessimism to stay with us that we do not get the idea that we can buck evolution in its attempt to eliminate the unfit. We should not constantly spend money, time, and energy, on attempting to improve those not capable of improvement.

We have survey reports, statistical studies, diagnoses, and indicated recommendations. These point the way towards prevention of delinquency. We can get a clearer picture of how heredity, environment, and the personality-at-the-moment have determined certain capacities and limitations. We can contact the asocial and antisocial types early in life and prepare them for adjustment in some group and at the level where each belongs.

It is the attempt of the individual to adjust himself in the wrong group or at the wrong level that brings disaster. We must remember that it is not only the defective that needs help towards finding his level and adjusting himself to it. Many an adult delinquent gives clear evidence that during childhood he might have been detected and should have been dealt with as having an over or under-acting nervous system: as being of unstaple emotional make-up, maybe given to explosions, irritability, apathy, sensitiveness, or moodiness; as a neurotic, not unlike many of our adult types; as an incipient dementia precox, or paranoid type; as one with a disturbed sex psychology; as of asocial or anti-social tendency.

All of these individuals would at least tend towards proper adjustment if the evolution of personality, and environmental factors were controlled in some degree.

209 Post Street.

DISCUSSION

JOSEPHINE A. JACKSON, M. D. (1955 Morton Avenue, Pasadena)—Dr. Catton's approach to this subject of dominant interest is both humane and sternly practical. That men of his type are bending their energies toward the solution of adult delinquency augurs well for the unfortunate individual and society as a whole. He tells us that maladjustment, which tends to crime, depends first on heredity, which, to me, is an insuperable argument for the sterilization of the unfit, beginning first with the criminal unfit and carrying it through all such members of society as are palpably incapable of transmitting a wholesome heredity.

This is not so much for the sake of society as for the sake of the wretched individual himself who must carry this inadequate equipment as a torturing ball and chain through all the days of his years.

Maladjustment results also from the lack of the right influences—psychic and material—in childhood.

Dr. Catton calls for intelligent control of the evolution of the child's personality. One means that presents itself therefor is to impress upon parents the significance of mental hygiene, which holds the total weight of weal or woe for the coming citizen.

Not dollars, nor erudition, but the faculty of adaptation is the child's supreme equipment. There should be a recognition by the masses and by all the wearers of white collars that more brains on the average top the overalls than top the white-collared mass. Manual dexterity means brains and assures adaptation.

ADELAIDE BROWN, M. D. (909 Hyde Street, San Francisco)—The increasing emphasis on habit-training in the hygiene of childhood must make a better poised adult life.

The fears of the dark, the need of a comfort to go to sleep with, of someone in the room, or of rocking to sleep—all these portend restless sleeping, an emphasis on the emotional and self-indulgent tendencies of the mind. The bad habit should not start, avoidance is easier than eradication.

Social adjustments can be taught early. Common courtesies of greeting, good-by, and thank you, mean self-control, appreciation of fellow-beings and social relations, and are thus far more than manners.

General physical and mental training, rather than specializing during adolescence, gives a control of brawn and brain on which body and mind may be developed later.

A social child, respecting his own and others rights, indicates mental guidance from birth. Of perfect specimens few grow, but many may be cultivated.

Ovarian Therapy—Emil Novak, Baltimore (Journal A. M. A.), emphasizes the fact that, rational as ovarian therapy appears to be in some conditions, the results are rarely striking and often nil to the level-headed observer. It cannot be assumed that a commercial extract can replace the normal ovarian secretion in the patient's body, or, for that matter, that it originally contains any of the active hormones of the ovary. Here lies the crux of the whole problem, whose solution will depend in large measure on the work of the biochemist. Until this day, the physician who uses ovarian therapy should keep his feet on the ground and not let himself be carried away by the exaggerated claims of those who have something to sell or the ill-advised and premature reports of honest but deluded professional colleagues who have not yet learned the dangers lurking in the "post hoc propter hoc" method of reasoning. As I once heard a wise man say, "Ought we to assume, if the administration of cascara relieves constipation, that the constipated individual had been a victim of hypocascarium?" There can be little question as to the future importance of ovarian therapy—as regards its present importance there is considerable room for discussion.

THE HABIT CLINIC FOR THE PRE-SCHOOL CHILD

By SYDNEY KINNEAR SMITH, M. D., *Oakland, Calif.*

There is, of course, no deep mysticism or any subtle psychiatric procedure employed, but only an attempt made to dispense common sense in small doses.

FROM what has been said by Dr. Richards and Dr. Anderson, one does not need to dwell further on the work of mental hygiene as touching childhood, its history, and recent manifestations in this country. Nor does one need to emphasize more fully to a group such as this the real need for such work. However, granting the need for juvenile mental hygiene advancement, we feel that in a symposium of this nature it is pertinent that we focus our attention for a part of the time on that vastly important period of two to six. Up to quite recently this strategic period has been solely within the scope of the pediatrician and not the psychiatrist. As psychiatrists we feel that the problems of these years are within our territory, and that with a psychological background, as well as a medical one, we can be of real service in this field. We feel that it is not a problem for the psychiatrist alone nor the pediatrician alone, but for both, working together.

Our knowledge of adult psychoneuroses has given us a better understanding of the psychological twists of childhood. There is reason to think that there are conflicts present in childhood which give rise to psychoneuroses similar to those of adults, possibly more simple in their structure. In looking more especially at habits, we do not feel justified in arguing that the presence of an unusual habit in childhood bespeaks an adult psychoneurosis or psychosis, yet we do feel justified in saying that many of these habits are indications of an emotional instability, which, if allowed to develop undirected, may well make for an inefficient adult adaptation. Failure on the part of an adult to adapt himself properly gives us alcoholism, drug addiction, delinquency, prostitution, convulsions, and a variety of other abnormal modes of meeting the tasks at hand. We feel that these reactional make-shifts may often be traced back to an inefficient reaction—a habit in childhood. If these conflicts—these poor adaptations to reality—can be met and coped with at four instead of forty, what a vast amount of discomfort—personal, social, and economic—we have saved the patient, his family, and the state. We are willing to rest our argument with this superficial indication of our position, feeling assured that you are in agreement as to the vital importance of the two to six period. Also I feel sure that in Dr. Catton and Dr. Harvey's consideration of these problems the connection between childhood mal-adaptations and behavior problems of later life will be stressed.

We are bringing to you a report of work accomplished in Oakland and in Berkeley, where we are unusually fortunate in having the necessary equipment and facilities for work, and where at the present time we have a fairly satisfactory child guidance machine—a group of clinics at the Oakland Health Center, at the Oakland Baby Hospital, and at the Berkeley Health Center. Each of these clinics is provided with adequate space, proper surroundings,

social service workers, a psychologist, and close contact with an established group of specialists for reference work. We feel that we may be justly proud in being able to present a working organization to the National Mental Hygiene Committee, and I believe the first real effort of this sort in Northern California.

We are modeling our work largely along the lines of the work done in the state of Massachusetts by Douglas Thom, where the name "Habit Clinic," to the best of our knowledge, was employed for the first time. The beginning was made in the city of Boston in a most unpretentious manner about two and one-half years ago. A large part of the work at first was done personally by Dr. Thom, later junior workers were drafted from the Boston Psychopathic Hospital, including a psychiatrist and a psychologist. The work has spread from this rather inconspicuous beginning and is now reaching well into the state. The ground for this work has been especially well broken in Massachusetts by a very complete and carefully executed program of mental hygiene. The first habit clinic in Boston included, as Dr. Thom points out, "a psychiatrist one afternoon a week, a pad of paper and pencil, a chair and table in the nursery, and the necessary equipment for making a complete physical and neurological examination."

Work not dissimilar to this had been done earlier in New Haven with Gessell, and I believe also in New York. But I think that we are correct in saying that the term "Habit Clinic" was employed in the Massachusetts undertaking for the first time.

What is the scope of a habit clinic? The province of such a clinic is to consider and treat improper modes of dealing with childhood problems—that is, within the period of two to six years. Also, we should include within this scope an attempt to aid in the formation of habits which will be of use in developing a well-rounded adult personality. To be specific, what are typical situations to be dealt with in a habit clinic for pre-school children? First, we have faulty adaptation to the feeding situation—vomiting when certain foods are given, rumination, regurgitation. Then we have faulty sleep habits—night terrors, sleep-walking, sleeplessness, bed-wetting. Masturbation is one of the most frequent of our problems. Dirt-eating, thumb-sucking, lying, cruelty, speech defects, day-dreaming, tics, undue affection for a member of family mannerisms, are but to mention a few of our situations.

To be more specific, I can summarize a few cases recently encountered.

Case I—Boy, aged 5. Complaint: Bed-wetting, running away from home, facial and nasal tic. As to the bed-wetting, we find that he is given water and tea in abundance at a late supper, is not sent to the toilet before retiring, and is scolded continually about this shortcoming. We try to cut out the scolding and to change the dietary and sleeping situation. As to the running away, we find that the child has an excessive fear of the father, induced by too frequent punishment, often considerably delayed after the offense. Due to this delay, the child has stored up a fear and a resentment for the father, and gets away from home when the father is about. The facial and nasal tics are on a physical basis in part. The child has large tonsils—a mild rhinitis is induced, the infection ascending to the eyes where a mild blepharitis is caused, the constant irritation in the nose causing the snuffing, and in the eyes the blinking. A removal of the tonsils has largely remedied this condition. Imitation also

plays a part here, for we find that the patient's older brother had a similar habit.

Case II—Boy, aged 5. Complaint: That he soils himself in kindergarten. In this case we find physically an underdeveloped child, with poor muscular tone. As a baby, and even later, we find that the mother worked out and the boy was left to the tender ministrations of an older sister. Very little attention was given to the bowel movements, and the child was not taught to go to stool at regular intervals. Our present trouble is largely a continuation of this untidy habit developed during babyhood.

Case III—Boy, aged 6. Complaint: Masturbation. Here we find a rather long foreskin with difficult retraction and evidence of irritation. Our first step is circumcision. We changed from a nightgown to sleeping-suits, and arranged for the child to sleep alone. We have also arranged that the child is not to be put to bed until there is evidence that he is sleepy; heretofore, the youngster going to bed immediately after dinner, before he was sleepy and lying there fully an hour before he went to sleep—a golden time to foster the habit we are trying to overcome.

Case IV—Girl, aged 5. Complaint: Stammering. The child had been somewhat slow in learning to talk. This was a source of annoyance to the parents, and they constantly urged her to talk, scolding her at times for being slower than their other children. Some well-meaning teacher told the mother to make the child repeat sentences as fast as possible. This was tried and the child's defect became much more pronounced. In our clinic treatment, we changed the type of therapy to include deliberate pronunciation and breathing exercises, and tried to establish the necessary rapport between the child and the examiner.

These cases I have summarized, not because there is anything very spectacular or remarkable about them, but rather to show you the type of thing we encounter in our habit clinic work, and to emphasize the types of disorder which we feel are worth remedying. We feel that therapy along these lines can make the difference between a normal adult and an adult defective in some emotional respect, possibly a dependent on state or county.

ORGANIZATION AND TECHNIQUE OF A HABIT CLINIC

In the first place, to my mind, the setting of such a clinic should be given most careful consideration. I feel very strongly that it should be located in an established clinic or nursery. For the proper handling of a clinic one needs the constant proximity of specialists in other lines, the internist, the surgeon, the oculist, and so on. A dentist also is an essential part of the general clinic personnel. The actual clinic surroundings should be carefully considered, so that as far as possible the child is freed from the usual terror of white-walled hospitals and outpatient departments. Ordinary nursery accessories should be in abundance—sand pile, toys, books, games, and, if possible, a competent director for these activities. While I feel that to a certain extent it is valuable to keep before the child the fact that he is coming to the physician for a purpose, yet we do want him to come in to us from as near a normal environment as we can provide. Toys in the examining room are useful at times. Small chairs and a small table are worth getting. Needless to say, examination paraphernalia should be inconspicuous.

We find it more satisfactory to discuss the situation with the parent before seeing the child (leaving the child with a nursery attendant). Then to have the child in with the parent, adhering largely to commonplaces rather than going directly to the

situation in question, or giving the mother an opportunity of covering the situation before the child, emphasizing, as she all too frequently tries to do, the fact that her child is a "nervous child," how he annoys the family, how many other members of the family have suffered from nervous complaints and such-like data, which, of course, tends to make the situation worse as far as our patient is concerned. Then, after a degree of rapport has been established, we like to see the child alone for a few minutes; this is not always accomplished until the second visit. These visits alone with the child, we feel, are of real value and often give us the clue to the situation. These sessions are of real therapeutic value, and it is a satisfaction to find that your small patients come to look forward to their clinic visits, and pride in the week's attainments prove of no small value in habit correction.

There is, of course, no deep mysticism or any subtle psychiatric procedure employed, but only an attempt made to dispense common sense in small doses. Usually, the mother must be very carefully instructed in the things to do, and more important, in the things not to do. And, most important, the social service worker or the visiting nurse should make repeated home visits to see that such instructions are followed. In many of our cases the cleaning up of the home situation automatically clears up the habit situation.

After dealing with the parent, the situation is gone over in as simple a way as possible with the youthful patient, pointing out frequently that the reaction complained of is immature, and not worthy of him. We try to dispel the all too frequent belief of the child that his habit is something of dire moment and consequence. We explain to him that, although it is not entirely admirable, yet it is not of the greatest importance and that we fully expect that it will disappear. Sometimes we outline simple lines of therapy for the child, breathing exercises, co-ordinating muscle movements, simple dance movements. Then, most important, we outline a program of positive attainments and aim at the establishment of a useful set of habits. A program of helpfulness in small duties about the home, conduct in kindergarten and in the playground is covered.

In outlining these positive situations, we are keeping in mind several salient points of child psychology, which we feel are worth mentioning in passing. These are: (1) Reasoning power of the child; (2) ability to imitate; (3) ability to accept and act on suggestion; and (4) the need of approval.

The power of reasoning in young children, especially in infants, has been a source of discussion for years, and we only want to point out that beyond doubt we give a young child credit for all too little intelligence. His mental processes are far ahead of his powers of speech, as anyone can verify who has had opportunity of watching children. In the practical management of children we find that an appeal to reason is often useful before a child can express himself. For this reason, it is poor policy to feel that we can fool a child with any silly explanation that comes to mind. It is much safer to err on the side of crediting him with too much intelligence rather than with too little.

As to our second point—the ability to imitate. This ability can be used as a real aid in building up a set of good habits and shaping a satisfactory character. A cheerful, bright, alert, interested mother will, in most cases find the same sort of child, whereas a surly, scolding, nagging mother cannot complain of a nervous child. If the family clothes are thrown hit or miss about the room on retiring, one cannot be surprised if Johnnie's clothes are likewise distributed. If the sleeping and eating habits of the family are slovenly, one must look for similar habits in the small boy of the family.

Our third attribute—the ability to accept and act on suggestion—is possibly our greatest asset in dealing with the problems of the nervous child. With ordinary suggestion, tactfully applied, we can induce habits of orderliness and precision in a child without any great deal of difficulty. It cannot be done immediately, but every success makes the next attempt less difficult. Suggestion is a real factor, if well used, but without common sense is useless. By this we mean, that, if a child of four is busily engaged in pulling the cat's tail, a mere soft-voiced suggestion that he stop this fascinating sport and come to dinner will not suffice, and, if anything, makes the situation worse. If, on the other hand, when his attention can be gotten, it is suggested to him that some other pursuit—eating his meal—is just what he most wants, his attention is taken from the cat, not focused upon it as it was in the first place, and the beginning made for a new and beneficial association. As has been pointed out in the case of army orders, the men are brought to attention before the order is given, not issuing it while their attention is on some other move.

Our fourth and last outstanding point is that very prominent desire for approval that every normal child manifests. Approbation and desire to hold the center of the stage play no small role in juvenile psychology and must be taken into account. Every child craves a certain amount of credit for work well done, and a well-rounded character will not result if this is not obtained. Too free an approbation is bad, but just praise well-applied helps more than the hair-brush. No child should be given a free lease on the center of the stage, but focusing family attention on the child, in moderation, is helpful. A too frequent repetition of the adage, "Children should be seen and not heard," is the cause of no few nervous disorders, and is conducive of a seclusive, shut-in make-up, which forms a breeding place for subsequent difficulties of adaptation.

We feel that the physical consideration should be large in habit cases. To be concrete, we feel that circumcision should be advocated at the least sign that it is needed. In normal children, we may frequently disregard this necessity, but with the nervous child, even a slight source of irritation may be enough to swing the pendulum in the wrong direction; consequently, circumcision may be neurologically indicated when it is not surgically so necessary. Tonsils and adenoids must go, with an accompanying removal of a variety of facial tics. Eyes should have early attention if there is any indication of muscle trouble. The orthopedist must frequently be consulted as to posture and deformity. Focal in-

fections should not be forgotten, although we do not feel justified in cottonizing many of our diminutive patients. Nutrition, too, is to be seriously considered.

A psychologist is an essential part of our clinic. For routine—Binet's—we care not a whit, but for intelligence tests, applied by a good medical psychologist, with an ability to interpret, results in light of special abilities and disabilities we have every respect and look to as a valuable adjunct of our clinic.

Frequent conferences should be arranged to include the psychiatrist, the psychologist, and the social service worker. This point cannot be overemphasized, for, without the fullest co-operation and understanding between these three viewpoints, we cannot hope for the fullest accomplishment of our aims.

In closing, then, if we may sum up the points considered. We have looked briefly at the development of the habit clinic idea in this country, with especial reference to the work in Massachusetts. Our next consideration was a general survey of a habit clinic, with resumé of typical cases. Our final division was a view of the actual mechanics of running a clinic, and our mode of procedure. I should like to close this paper with the words of former Chief C. Macfie Campbell:

"For the nervous child two conditions are eminently salutary: First, a wholesome objective regime, and second an atmosphere of frankness, in which he can get a fair chance to discuss his troubles."

1904 Franklin Street.

A Method of Demonstrating Tubercle Bacilli in the Urine—In the method described by Stephen G. Jones, Boston (Journal A. M. A., December 13, 1924), a catheterized specimen of urine is centrifugated at lowest speed for two or three minutes, thereby removing the bulk of the pus and detritus. The supernatant cloudy fluid, containing a few pus cells and the bacilli, is poured off, one-half is discarded and the remaining half is poured into a second centrifuge tube. To this half-filled tube, one-quarter volume of 95 per cent alcohol is added, the remaining quarter being distilled water. This mixture is centrifugated at highest speed for forty-five minutes until clear, the supernatant fluid discarded, and a smear made from the sediment obtained with a flamed wire loop. The smear is allowed to dry and is then fixed by being passed rapidly two or three times through a Bunsen flame. The centrifuge must be an electrically driven high speed machine. When carrying a load of four tubes, it should make from 2000 to 2100 revolutions per minute, which produces a force 1077 times that of gravity. The Ziehl-Neelson stain is employed. A more delicate stain is obtained if a steam bath is used rather than heating the smear with the direct flame. This is easily accomplished by placing the glass slide over the open top of a can containing steaming water. In this way the stain is heated sufficiently without danger of precipitating the dye. Twenty minutes suffices. The preparation is decolorized by exposure to 30 per cent nitric acid, followed by alcohol (Czaplewski's solution) or to 20 per cent sulphuric acid. The pitfalls are that occasionally nitric acid and alcohol may not decolorize all acid-fast bacilli other than tubercle bacilli. Twenty per cent sulphuric acid will decolorize all other acid-fast bacilli, but may also decolorize tubercle bacilli. The decolorized smear is washed with water, and counterstained with methylene blue. Several hours' search will often disclose the solitary group of bacilli which otherwise will be missed.

Adam and Eve were perfectly happy and sweetly contented in the garden of Eden until Satan's prescription was taken and they beheld their naked condition and Eve began making garments of fig leaves and both of them were ashamed of themselves.—Austin Flint (Iowa Medical Journal).

THE PNEUMONIC PLAGUE IN LOS ANGELES

By EMIL BOGEN, M. D., *Los Angeles*

A story of the recent epidemic which demonstrated the effectiveness of intelligent health work.

ON OCTOBER 29, 1924, a physician called up the Los Angeles General Hospital to say that he had just seen a Mexican patient who appeared to be critically ill of some malady which he could not definitely diagnose, but which he thought might be highly contagious, since several others in the neighborhood were similarly affected, namely, with a very high fever and pains in the back and chest. Accordingly the ambulance was sent to a Mexican settlement on the outskirts of Los Angeles, where a group of people were found clustered in front of a one-story frame building with a little porch and a single front room.

In the middle of this room an old Mexican woman was lying on a large double bed, crying between paroxysms of coughing, while along the wall was a couch on which was seen a Mexican man of about 30 years of age, restless and feverish, but not coughing. There were several other persons of both sexes in the room, one of whom volunteered to act as interpreter. With his aid, it was learned that the man had been stricken the preceding day with a severe pain in the front of his chest and along the entire spine, and had had a fever, which at that time was 104 degrees, and a few reddish spots on his chest, but no other symptoms of note. The old woman had apparently been previously stricken in the same manner, but she had been coughing for the past two days, expectorating a profuse bloody sputum, and had loud, coarse rhonchi in her chest.

While these two patients were being placed in the ambulance, the interpreter led to a house nearby, where he said there were some other patients with the same disease. Here a young man was found in bed, suffering with a high fever and pain in the chest and back, but no other symptoms. In an adjoining room his wife, also feverish, stated that she was feeling better than previously, while in the front room a young girl sitting in a settee, with her head in her hands and with a flushed face, insisted that she was not sick, only a little tired. (Three days later the man was dead, and the two women were dying in the hospital.) The interpreter remarked that four other boys, relatives of our patients, were ill at this time in their home a few blocks away. He added that the father of the man we had come for had died in the hospital a week ago of what was thought to be pneumonia, and that the mother had died a week before that with similar symptoms.

The four boys were brought to the hospital that same night, and during the following day six more cases were admitted from that neighborhood. Soon after admission they developed signs of a severe pneumonia, with bloody expectoration and marked cyanosis. During this day three of them died, and that afternoon the diagnosis of pneumonic plague was first suggested. The following morning Dr. George D. Maner performed an autopsy on one of the patients who had succumbed, and reported that smears from the lungs of the patient showed Gram-

negative bipolar staining bacilli characteristic of plague.

During the next six days twelve other Mexican patients were admitted with the same condition, but deaths followed so rapidly that, by the end of the week, out of the entire group there were only two boys left alive, and one of these passed out during the next week. Seven other patients have been reported to have died of the same disease without entering the hospital, making a total of thirty deaths from the pneumonic form of plague during the two weeks in Los Angeles.

On October 31, the day that the organism was first found, a nurse who had been caring for the first victim during his few hours in the pneumonia ward the previous week was admitted to the hospital, suffering with a severe pain in the chest and back and a fever which she said had been coming on for two days. Soon she developed difficulty in breathing, coughing and expectoration, which on the following morning was blood-stained, and a large, painful swelling of the glands of the neck. As a desperate resort, she was given 30 cubic centimeters of a 1 per cent solution of mercurochrome intravenously, and during the week received several additional injections, with noticeable improvement in her condition, and appears at the present time to be proceeding towards convalescence. As yet, however, no bacteriological confirmation of the diagnosis has been secured in this case.

As soon as the disease was recognized steps were taken to prevent the spread of the epidemic. The district within which the cases originated was placed under quarantine, and all persons known to have been in contact with patients were observed carefully for the next ten days, the maximum expected incubation period. An organized campaign was inaugurated against rats. At first everyone in the hospital wore a clean gown, cap and gauze mask whenever he entered a room in which a plague patient was being cared for, but this was deemed insufficient protection, and so masks were made consisting of a pillowslip which was placed over the entire head, a small piece being cut out for the eyes, which was replaced by a piece of transparent celluloid attached by means of adhesive plaster. Procuring and working in these masks was a matter of considerable exertion, and also of considerable comment and diversion.

Meanwhile about a score of patients had been placed in the contagious building, with a diagnosis of "suspected" plague which could not be confirmed. A number of these were proven at autopsy to have died from some other condition, while the subsequent clinical course of the others tended to clear up the diagnosis. One case of pestis minor, however, with a bubo which proved on aspiration to contain organisms of plague which were confirmed by animal inoculation experiments, was found in this group.

On account of the prostrated condition of most of the patients and the difficulties incident to caring for such an unexpected and dangerous disease, the histories and records are necessarily incomplete and inadequate, but the following data regarding the twenty-four patients who died of pneumonic plague

at the Los Angeles General Hospital may be of interest. In every case a history of close contact with a case previously stricken could be secured. The average duration of the illness before admission to the hospital was between three and four days. The average length of hospital treatment was less than two days, but one case was proven plague at autopsy after twelve days of hospitalization.

The chief symptoms complained of, in the order of frequency of occurrence, were fever, ranging from 100 to 106 degrees on admission, expectoration with blood-stained sputum, cough, pain in the chest, headache, generalized pains, vomiting, pain in the back and upper abdomen, malaise, epistaxis and chilliness without rigor. The main findings on physical examination, in the order of frequency, were large, coarse rales in the chest, thickly coated tongue, reddened throat, dyspnoea, impairment of percussion note over the chest, restlessness, prostration, delirium, weak rapid pulse, cyanosis, a systolic murmur, localized adenopathy, conjunctival injection, increase in spinal fluid pressure, with signs of meningismus in the children, jaundice and a macular rash.

Unfortunately, only nine of the bodies were autopsied before cremation, all of whom showed typical findings of a confluent bronchopneumonia in widely varying degrees, with the signs of a very severe infection, and the recovery of the bacillus of plague from the lungs and other organs, as proven by guinea pig inoculation. Blood cultures from nine other patients, however, also yielded this organism. In the remaining cases no bacteriological studies were made, but the clinical history and course of the disease, as well as the evidence of transmission through them to other patients, leaves no doubt as to the diagnosis. Smears from the sputa in a number of instances showed Gram-negative bipolar staining bacilli, with comparatively few pus cells.

In addition to repeated stimulation and other symptomatic treatment which all of the patients received, more than half of them received intravenous (or intraperitoneal) injections of mercurochrome, including the nurse and the boy who still survive, but fresh anti-plague serum was secured only in time to be used in one case. Since no new cases of pneumonic plague have developed for four weeks, it is believed that the epidemic is over, though sporadic cases of the bubonic type may still be expected to appear occasionally.

What's in a Name—Occupational therapy is now a classical remedy for ennui. It used to be called "work." The new name makes it more effective. An unfriendly dame suggests the installation of an old-time tread mill in every home as an economic proposition. It would serve both as a domestic power plant and an efficient substitute for cow pasture pool.—Kansas Medical Journal.

As an Editor Sees It—"Doctors who specialize are valuable. They push the science ahead. They do things that non-specialists could not do. But progress in one direction is paid for by loss in another. We are losing the first-rate all-around general physician and consultant. Properly speaking, the specialist should only be an assistant to the general physician, called upon when required."

ADENOMA OF THE THYROID *

By VINTON A. MULLER, M. D., Reno, Nevada.

A clinical study for clinicians.

The treatment of adenomas is surgical. Iodine is contra-indicated.

The use of the x-rays in this type of goitre is to be condemned.

DISCUSSION by W. W. Washburn, San Francisco; M. R. Walker, Reno, Nevada; Raymond St. Clair, Oakland; Thomas Wilbur Bath, Reno, Nevada.

THE adenomatous goitre, which is the most common type of goitre, produces thyroid enlargement by the growth within the substance of the thyroid gland of encapsulated adenomas, which may be either single or multiple, and which give rise to the condition frequently spoken of as nodular goitre. The true etiology is as yet unknown, though it is quite commonly believed that some of these adenomas take their origin in cases of long standing colloid goitre, whereas others are believed to develop from foetal rests.

Adenoma of the thyroid ordinarily makes its appearance between the ages of 15 and 20, although some of these growths are first noted later on in life. The average age of first appearance is 22. Clinically, it is characterized by an asymmetrical or nodular enlargement of the thyroid gland caused by the presence of single or multiple growths, which may be confined to one lobe, both lobes, or any portion of the gland. At times these goitres may be retrosternal and not particularly visible in the neck or, in addition to the enlargement in the neck, one may find that one or more of the adenomatous masses descend behind the sternum and into the mediastinum. Asymmetry, though usually present, may not be marked, and occasionally only the most careful palpation will reveal the presence of a tumor mass or multiple masses within the gland. To the palpating finger the consistency of an adenoma is usually harder than normal thyroid tissue, but where degeneration has taken place the consistency may vary from the fluid of cyst formation to the hardness of calcareous deposits. Degenerative changes are prone to occur and are usually the result of hemorrhages within the capsule of the adenoma, and give rise to the various clinical varieties, such as hemorrhagic goiter, cystic goitre, calcareous goitre, etc. Myxomatous and hyaline changes also occur. In case of sudden enlargement, one must always think of hemorrhage; in case of rapid growth, malignancy.

In the early stages of their development these goitres do not produce symptoms except when their location is adjacent to an important structure whereupon pressure symptoms may develop. These pressure symptoms will depend upon what structure is involved, and are commonly manifested by difficulty in breathing or swallowing. Large retrosternal growths may interfere with circulation, produce a caput medusa or other signs of mediastinal obstruction.

About sixteen years after the appearance of the adenoma within the thyroid symptoms of hyperthyroidism may develop. The average age of appearance of these symptoms is thirty-six and one-half

* Presented before the Twenty-first Annual Meeting of the Nevada State Medical Association.

years, though at times young patients twenty-eight and thirty will come in mildly toxic. The cause of this hyperthyroidism is due to the secretion of normal, or nearly normal, thyroid hormone in excessive amounts by the adenoma. In 1916, Goetsch believed that the mitochondria in the adenomas were increased when hyperthyroidism was present, and offered this as a means of differentiating pathologically between adenomas with and those without hyperthyroidism, but his work has not been confirmed. In 1920, Boothby stated that, pathologically, there was no difference between an adenoma with and one without hyperthyroidism. In 1922, Wilson found that in the adenomas with hyperthyroidism there was evidence of increased activity of the parenchymal cells, which was indicated by moderate degrees of cell hypertrophy and hyperplasia which was not present in adenomas without hyperthyroidism. He concludes that the symptoms of hyperthyroidism occurring in these adenomatous glands are caused by the absorption of complete thyroxin in previously stored colloid, which is being manufactured more rapidly than in a normal gland, but much more slowly than in the gland of exophthalmic goitre.

These symptoms of hyperthyroidism are evidenced by nervousness, tremor, tachycardia, loss in strength and weight, with a tendency to hypertension and, in the later stages, myocardial degeneration. This type of goitre has a more pronounced selection for the cardiovascular system than exophthalmic goitre, and the changes produced are gradual, progressive, and certain. These patients appear for examination on an average of nineteen years after the first appearance of the goitre, and three years after the onset of their symptoms of intoxication. Nervousness and tremor are always present, but to a less degree than in exophthalmic goitre, whereas the cardiovascular symptoms are more pronounced; and it is not especially infrequent to see patients with oedema of the feet and ankles with all the symptoms and signs of cardiac decompensation who have been treated for cardiac decompensation "and the small, nodular goitre, which has been there for years without causing any trouble," overlooked. The tendency to hypertension is greater than in Grave's disease. Both systolic and diastolic pressures are greater than in Grave's disease, and this is true both for office readings and bedside readings, although in my own personal experience cases of Grave's disease seem to have higher systolic pressures than toxic adenomas. The basal metabolic rate is increased in the toxic adenomas, but this increase is to a less degree than in Grave's disease. The average B. M. R. in 201 cases studied by Boothby was plus 28.

The treatment of adenomas is surgical. Iodine is contra-indicated. Its use exerts no influence in causing the adenoma to disappear, but, to the contrary, it may cause symptoms of hyperthyroidism to develop; a condition which was often called by our predecessors "iodine heart."

The use of the x-rays in this type of goitre is to be condemned. They do not relieve the patient of her adenoma, but may relieve her of what normal thyroid tissue she has left and thus give rise to symptoms of hypothyroidism. The adenomas often crowd out and obliterate the normal thyroid tissue until

there remains only a thin layer of it adhering to the capsule of the gland which might be just enough to care for the patient's needs after her adenoma is removed. In some of the adenomatous goitres that appear diffusely enlarged, an x-ray treatment will cause the adenomatous nodules to become apparent by its selective action on the extra adenomatous tissue.

Cleaning up of foci of infection seems to have a beneficial influence in Grave's disease, but will not exert any effect in causing an adenoma to disappear.

To remove the adenoma surgically is to remove abnormal thyroid tissue, which, by its presence, produces all of the patient's symptoms. Its surgical removal will put a stop to the disease, but whatever permanent damage to vital organs has occurred will always remain. Even the extreme cases, however, will show some improvement after operation. Removal of the goitre before symptoms arise preclude their possibility; removal after they appear, arrests the disease, prevents further degeneration and allows for some recuperation. The B. M. R. returns to normal limits within two weeks following removal of the adenoma. In contra-distinction to Grave's disease, these patients do not require the pre-operative preparation that those suffering with Grave's disease do—the advanced cases with myocarditis, auricular fibrillation and hypertension, naturally require pre-operative rest in bed and digitalis, until such time that they may be able to withstand thyroidectomy. Preliminary ligations are never done. It is essential that we recognize adenoma of the thyroid and remove them surgically before permanent damage to vital organs takes place. It is not good judgment, however, to advise surgery in young people from 15 to 25 years of age without symptoms, on account of the possibility of new adenomas developing after operation or very small ones being overlooked at the time of operation, to subsequently grow and give trouble. A frequent site of such "recurrences" is the pyramidal lobe, and for this reason it should be removed at operation, providing there is enough normal thyroid left without it.

A further, but also important, reason for advising surgical removal of adenomata of the thyroid gland is that 95 per cent of cases of carcinoma of the thyroid occur in glands with pre-existing adenomas, and, although carcinoma of the thyroid gland is rare, we can readily see that it may be made rarer by curing our patients of adenoma.

Gray-Reid Building.

DISCUSSION

W. W. WASHBURN, M. D. (380 Post Street, San Francisco)—I am glad that Dr. Muller has chosen to speak upon a distinct type of goitre rather than attempting to cover a large field. He is to be commended for this excellent paper, treating with adenoma of the thyroid.

The importance of first establishing an accurate diagnosis cannot be too strongly emphasized, for upon the diagnosis depends proper treatment. We still continue to see altogether too many goitres treated in a sort of "routine" manner. If iodine doesn't help, X-ray is tried, and when medical measures fail some of these patients are told that nothing more can be done except a "dangerous" operation. And, too often, I am sorry to say, the general practitioner attempts treatment of these too long, before referring them to one familiar with goitre problems. One still continues to see a great many adenomas of the thyroid treated along medical lines, especially the x-ray. This is because either an accurate diagnosis has not been

made, or else the physician is not aware that adenomas are neither cured nor benefited by x-ray therapy.

When seeing a young woman in the second decade of life presenting definite adenomas of the thyroid and symptoms of hyperthyroidism, before attributing this hyperthyroidism to an overfunctioning adenoma, one should suspect an associated hyperplasia in the remaining gland, as ordinarily the adenoma does not put out increased amounts of thyroxin until it has existed a number of years. True exophthalmos does not occur with toxic adenoma, and when present means a hyperplasia. A definite bruit heard over the thyroid gland proper, especially in the upper poles, is pathognomonic of hyperplasia. Toxic and non-toxic adenomas do not give a bruit upon auscultation, nor a thrill upon palpation.

The importance of exposing the entire gland at operation and palpating same cannot be too strongly emphasized. The full Kocher collar incision should be used in all cases, particularly when operating for adenomata. Recurrences after operation are generally due to overlooking small adenomas at the time of operation.

In reference to pressure symptoms from adenoma, I wish to call attention to the fact that we should not overlook some of the pressure signs. Chief among these is unilateral laryngeal palsy, which may have come on so gradually as not to have caused distinct voice defects, due to compensatory reaction of the opposite vocal chord. A pre-operative laryngoscopic examination will readily disclose the presence of such conditions, and relieve one of the embarrassment of having a voiceless patient, in case the opposite laryngeal nerve is accidentally injured in the course of operation.

As pointed out by Dr. Muller, why not operate upon these patients in the earlier stages, when the operative mortality is practically nil, rather than wait until they become poor surgical risks, due to a badly damaged myocardium?

M. R. WALKER, M. D. (Gray-Reid Building, Reno, Nev.)—We all enjoyed this paper; it is brief and to the point. In our state, goitre is very common; apparently, at least, on the increase, although we have no reliable statistics to refer to. Diagnosis is not always easy, yet absolutely essential, if we expect to benefit our patients with any line of therapy.

While there is no question that surgery is the choice, there are numerous patients that, for one reason or another, will not submit to an operation. With such I have found that radiation will give at least symptomatic relief; especially is this true for relief from toxicosis.

Again, I observe that operation is by no means always satisfactory. I have recently had two patients who are now regretting that they submitted to an operation; one of them, within forty-eight hours after the operation, developed severe tetany. It is now over two years and no indications that we may stop treatments for tetany. This operation was performed by an able surgeon. The other patient has become asthenic and has developed a marked irritability of the heart, and, in spite of all I have been able to do, she has not regained sufficient strength to do her housework with any comfort—only two in the family at that. I have found that often the giving of thyroid or parathyroid is of advantage.

I feel that we should urge prophylactic measures more strenuously than we are in the habit of doing.

RAYMOND ST. CLAIR, M. D. (Medical Building, Oakland, Calif.)—Dr. Muller is to be congratulated on his paper.

In the simple adenomatous goitre, it has been my experience that the diagnosis is comparatively easy. It is in the mixed type that we have difficulty in arriving at the right diagnosis. I believe that in the majority of colloid goitres small adenomas are present in the gland. These on account of absence of symptoms are overlooked in the histories. In many of my patients who have come to me with adenomatous goitre with hyperthyroidism, I obtained a history of greater enlargement of the gland in the first years of their disease. In my experience the adenomatous type of goitre is not overlooked as often as the exophthalmic type, as many doctors who served in the late war will bear witness. In our organization there were three doctors who were suffering with exophthalmic goitre who had not previously been diagnosed.

I quite agree with Dr. Muller that surgical treatment, if done properly, is the one indicated in adenomatous

goitre, and if done early, soon after the toxic symptoms are noted, before permanent damage has occurred, one's results are practically 100 per cent cure. There has been a great deal learned about treatment of goitre in the past fifteen years, and our results are much better now than at that time.

The pre-operative care of the patient suffering with adenomatous goitre with hyperthyroidism is extremely important. It is my practice to get patients in the best possible condition for the operation, which is similar to the preparation in exophthalmic goitre; that is, rest in bed, good nutritious food, and a competent, quiet nurse, and digitalization. In the extremely bad cases I use the Crile method, with which you are all familiar. I can recall at least two or three patients with extremely bad symptoms in which this method was entirely successful.

It is not necessary to say very much regarding the post-operative treatment in simple adenomatous goitre patients who have suffered but a short time from hyperthyroidism, as they usually regain normalcy very quickly; but in those patients who have suffered permanent injury to their heart, kidneys, etc., it is necessary to keep them under observation for a longer period of time.

In patients who have come to me after having received x-ray treatment I have found difficulty in operating, on account of adhesions about the capsule. In some instances the patients have claimed that their symptoms had increased following its use. I am not prepared to say whether there is or is not a possibility of destruction of the small amount of normal gland which we find in these long-standing cases of adenomatous goitres producing a hypothyroidism, which is not a pleasant thing to have.

THOMAS WILBUR BATH, M.D. (Reno, Nev.)—It is always a privilege to listen to a discussion which affects public welfare. Formerly, appendicitis was discussed at nearly every medical meeting. Result: Today, most of the intelligent laity believe that the best place for a troublesome appendix is in the pickle-jar of the pathologist. Likewise, the public is becoming educated on such subjects as cancer, focal infections, and the better care of women in childbirth. Just now our efforts are directed along the line of goitre. Continuous discussion will increase our knowledge. For, as it has been well said, in a multitude of counsel there is wisdom.

Medical surveys that have been made in the United States and abroad have been illuminating, in that we have learned more concerning past geologic conditions, community inbreeding and localization of areas where goitre is endemic.

It is well to begin with a clear definition of the term goitre. Goitre means a diseased thyroid gland. There are many types of disease of this gland, but in the subject under discussion, as is well pointed out by Dr. Muller, the adenomatous is the most common of all. Just how many people in the United States have goitre we cannot say. But it is safe to assume that the number must be up in the tens of thousands. Every goitrous person is likely to become, unless aided, a serious deviation from normalcy. Why the disease is more preponderating among women we cannot say, unless it is the incidence of sex. There is an old saying in England concerning the child-bearing woman, that for every child she loses a tooth. That we would term a sex incidence. To the sex incidence we might ascribe the invasion of infection in women, which accounts for them having the first honors in goitres and bad gall-bladders.

In this connection, also considering the more underlying causes of goitre such as the deiodinization of endemic areas, we must always bear in mind the aggravating effects of such focal infections as bad teeth and tonsils. And especially that type of the shining sepulchre of bad dentistry known as the gold crown. The gold crown truly covers a multitude of evils. The constant drainage from the mouth into the cervical areas directly or indirectly affects the lymphatics of the thyroid, greatly contributing to heighten the pathology of the gland.

I think it will bear investigation that another contributing cause of enhancing goitrous conditions is child-bearing. Every wife is a possible mother. Parturition increases every normal function, and likewise sets in motion any abnormalcy. Repeated child-bearing will eventually wreck the frail life bark of the goitrous woman, and she will be lost upon the rocks of a destructive pathology. To her husband and friends who fail to correctly inter-

pret her condition, she is a neurotic; and she receives no sympathy because of her peculiar actions, when in reality the poor woman is traveling that vague borderland where illusions are real and distress is actual.

In summing up the treatment for this condition, as was well said by some of my confreres, the only treatment is surgical. The technique for this operation is now standardized. The mortality is much less than in appendectomies. The results, in the main, are quick and gratifying. Other therapy has been proved a failure. When the thyroid has become adenomatous, nature displays for common gaze her danger signal so that he who runs may read. And the interpretation thereof is removal.

DOCTOR MULLER (closing) — I shall endeavor to make my closing remarks brief, and will dwell only on a few of the points brought out in the discussion. One of the most important things, I believe, is the laryngoscopic examination, as mentioned by Doctor Washburn. In fact, this is of sufficient importance that it should be recommended as a routine procedure in the examination of all patients with adenoma.

The question of radiotherapy being contra-indicated in adenoma of the thyroid has been generally agreed upon. In those patients wherein relief has been afforded by this method of treatment, I would be inclined to believe that the symptoms of hyperthyroidism had come from an associated hyperplasia rather than from an overactive adenoma. It is a well-known fact that radiotherapy may exert a beneficial influence in toxic hyperplastic goitre.

Occasionally one does see poor results following surgery, but these instances are today so rare that they should not in any way influence the practitioner against advising surgery. If the adenoma is broken into and only partly removed, or if adenomata are overlooked and left in the gland to give rise to subsequent "recurrences," the result of operation will not be satisfactory. If all, or nearly all, of the normal thyroid tissue is removed with the adenoma, the characteristic symptoms of hypothyroidism will follow. Where we have large adenomata there is often very little normal thyroid tissue present. The adenoma is always encapsulated, and in operating one should exercise care to remove it wholly and intact with its capsule, but care should also be exercised to prevent the injury or removal of normal thyroid tissue. In those cases with small adenomata there may be quite an abundance of normal thyroid present, and this danger, therefore, becomes less. Injury to the recurrent laryngeal nerves and parathyroid bodies should not occur if one keeps within the capsule of the thyroid gland posteriorly, as these structures lie posterior to the capsule. Removal of the parathyroids or destruction of their blood supply which comes from the inferior thyroid arteries will result in tetany. Where tetany occurs, 10 cc. of a 5 per cent solution of calcium lactate in 100 cc. of normal saline should be given intravenously at once.

It is generally believed that focal infection or child-bearing does not play any part in the etiology of adenoma of the thyroid gland. However, they are very important factors in some of the other types of goitre with which this paper does not deal. The foetal adenomata undoubtedly arise from Wolfer's rests, which are laid down in intrauterine life, whereas the adult type most probably arise from cases of long-standing colloid goitre. Although it is always desirable to clean up foci of infection, one should not expect to see any change in his cases of adenoma following this means of treatment.

"A matter that is neglected to a very large extent by all our medical associations and our medical colleges is that of ethics. We need more preaching and more influence that will bring about right thinking in the practice of medicine. We are altogether too prone to overlook breaches of ethics and propriety on the part of some of our members; and bad conduct on the part of a few reflects on the whole medical profession. Oftentimes unethical conduct is due to ignorance. Our colleges, societies, and journals devoted to medical practice," says A. E. Bulson (Bulletin A. M. A.), "should emphasize the importance of adhering to the code of ethics as laid down and accepted by the American Medical Association."

SURGICAL TREATMENT OF CHRONIC PEPTIC ULCER

By J. H. BREYER, M. D., Pasadena

Review of recent literature.

An attempt to determine the relative value of medical and surgical treatment.

Many ulcers heal without any treatment.

Recent ulcers should be treated medically; all other types should be given the benefit of thorough medical treatment until cure or chronicity is established.

After failure of medical treatment, surgical interference should be resorted to without further delay.

After convalescing from operation, patient should be turned over to physician for management.

Successful treatment of peptic ulcer requires combined judgment of the physician and the surgeon.

DISCUSSION by Walter B. Coffey, San Francisco; Frederick A. Speik, Los Angeles.

THERE is still wide difference of opinion between some physicians and surgeons, as to the value of surgical treatment in peptic ulcer. Much of the older literature written has become obsolete. A review of the more recent literature may help us to arrive at some definite conclusions. From it and my own experiences I shall attempt to determine the relative value of medical and surgical treatment, and the indications for each.

Our knowledge of ulcer has been greatly increased in the past ten years by the study of living pathology in the operating-room and by developments in the radiology. Autopsy studies have revealed that many peptic ulcers heal without any treatment whatsoever. Experimental ulcers in animals usually heal very promptly, in spite of the presence of one or more producing causes. Why some ulcers become chronic in man is still not definitely understood. The following explanations perhaps carry us as far as any toward the solution of the problem.

When the gastric or duodenal mucosa, lowered in vitality from any cause, is exposed to the digestive action of gastric juice the surface becomes eroded. The degree of erosion depends on the vitality of the mucosa and upon the general powers of resistance of the individual. The lowered local resistance may be due to some circulatory disturbance of the gastric or duodenal mucous membrane, to a trauma, or to a general or local infection. The lowered general resistance of the patient may be due to anemia, poor nutrition, or to some nerve strain, such as worry, that may influence the high acid content of the gastric juice and thereby be a factor in producing pylorospasm. The eroding action of gastric juice is nil in the absence of hydrochloric acid, but the mere lowering of the hydrochloric acid content does not diminish the peptic activity of the gastric juice. When the stomach does not empty itself in normal time, we have a prolonged contact of the acid gastric juice with the eroded area, as well as the irritating action of decomposing gastric contents. A true vicious circle is often established, the ulcer maintaining all the conditions that caused it.

The following conditions have a natural bearing on the history of an ulcer. Rebellious chronic ulcers are more frequent in males than in females. In young subjects there is less tendency for the ulcer to become chronic; in older individuals the reverse is true. The location of the ulcer has a distinct bear-

ing on chronicity. A pyloric or pre-pyloric ulcer is apt to be tenacious because of the spasm which it produces. Duodenal ulcer is about four times more frequent than gastric ulcer. One report states that, out of a total of 262 duodenal ulcers, 242 were located within five centimeters of the pylorus. Out of 633 cases of gastric ulcer at the Mayo Clinic, the ulcer was located on or around the lesser curvature 534 times, 85 were in the posterior wall, 9 involved the greater curvature, and 5 were in the anterior wall. Of those on the posterior wall, 8.2 per cent were in the pyloric third, 73.3 per cent in the middle third, and 16.5 per cent in the cardiac end. Seventy per cent of gastric ulcers, when healed, produce contractions which result in some degree of stenosis.

Healing takes place by proliferation of the connective and glandular tissues. The muscularis never regenerates. The continuity of the muscle fibers is interrupted by fibrous tracts, and the stomach wall loses its pliability. These connective tissue fasciculi eventually contract more or less. When the wall of the stomach has been perforated, or when the inflammatory process has reached the subserous layer, the peritoneum becomes irritated and protective adhesions with adjacent viscera result. Chronic gastric ulcers nearly always have craters; the majority of duodenal ulcers lack this characteristic. The old callous ulcer of the stomach, with hard indurated margins, is very apt to recur.

What is known of the etiology and pathology of ulcer indicates that all that medical or surgical treatment can accomplish directly, toward promoting the reparative process, is to remove such hindrances to healing as may exist. In the majority of cases where the ulcer is active the main object is to control the acidity and to place the stomach at rest by avoiding all causes of irritation. The general condition of the patient must be studied and improved. Food traumas are lessened by proper diet. Intra-gastric tension, fermentive processes, and prolonged gastric juice contact are reduced by abolishing stasis. All foci of focal infections must be cleared up. Efforts to reduce the nervous tension of the patient must be made by advising him as to errors in his social habits and daily routine. Psychic rest is as important as physical rest, in reducing secretory and motor disturbances.

A careful analytical study of the Sippy medical treatment compels one to admit that it meets all of the above conditions. It is rational and logical. It goes without saying that all recent ulcers should be treated medically, and all other types should be given the benefit of thorough medical treatment until cure or chronicity is established. Each ulcer case must be considered individually. Treatment should not be carried out with an empirical routine. A definite knowledge of all the facts must be obtained. The history should be very carefully gone into. A case that is of long standing, with a history of many recurrences, should be investigated as to the extent of the pathological process. It should be determined whether or not the ulcer is of the indurated, callous type, which experience has shown does not yield to medical treatment; whether the ulcer is situated at or near the pylorus, causing obstruction and deformity, which type, as a rule, cannot be

completely healed by medical treatment alone; or whether any of the complications of ulcer, such as acute or chronic perforation, repeated hemorrhage, hour-glass stomach, or perigastric adhesions have already taken place.

If the diagnosis of ulcer can be made early a higher percentage of cures will result, but care must be exercised not to misinterpret the symptoms of a diseased gall-bladder or appendix for those of ulcer. The interrelationship between ulcer of the stomach or duodenum and disease of the appendix or gall-bladder should never be forgotten. It is as important to clear up the focal infection of appendix or gall-bladder as those located elsewhere.

With the above points in mind, the physician and the surgeon will get closer together in their treatment of ulcer. The cases will be classified, with regard to treatment, into more definite distinct groups. It is only after failure of medical treatment that surgical interference should be proposed, in which case it should be resorted to without delay, otherwise its benefits will be gravely compromised. Likewise, after convalescence from the operation, all cases should be turned over to the internist for thorough dietary management.

The most frequently employed operation for chronic duodenal or gastric ulcer is posterior short loop gastro-enterostomy, the stoma being placed at the most dependant portion of the stomach. In the absence of an organic obstruction, it is probable that a more or less immediate spasm of the pylorus follows the operation of gastro-enterostomy. This pylorospasm prevents the gastric contents from passing into the duodenum, and as a result the gastric juice and food pass in the direction of least resistance through the new opening. After healing of the ulcer is well under way, the spasm probably relaxes in the majority of cases, and more or less of the food again passes through the pylorus. The safety-valve action of the new opening prevents excessive intra-gastric tension. Food fermentation is prevented by freer emptying of the stomach, and the regurgitated bile and pancreatic juice bring about a neutralization of the gastric contents. In properly selected cases the percentage of cures has been augmented by further surgical procedures. The removal of the ulcer seems ideal and logical; the risk, however, is increased. The Balfour cautery method is the operation of choice when it can be done without too great danger or chance of resulting deformity. In ulcers of the callous type, situated near the pylorus, and in which the possibility of carcinoma must be considered, Billroth's No. 2 excision for ulcer, with posterior gastro-enterostomy, is the method of choice. Moynihan and others are extending this operation to all ulcers in the region of the pylorus, with very good results. The Billroth excision operation definitely accomplishes three things. It removes the ulcer, thus abolishing secretory reflexes as well as a potential cause of cancer; by removing the pylorus it eliminates pylorospasm; and by lessening, to a considerable extent, the secreting area of the stomach it diminishes the free hydrochloric acid. Excision of the ulcer, together with pyloroplasty, is an operation that is also in high favor. To carry out either of these last-named procedures, the patient

must be sufficiently strong to withstand a long and possibly depressing operation. Too much emphasis cannot be laid upon this point. When the patient's condition will not permit of a more radical procedure, a secondary operation at a later date may be necessary to produce the best results.

There is no doubt that ill-advised surgery has been performed, with disastrous results, upon patients who did not have either duodenal or gastric ulcer, and also that these patients had previously been treated medically for ulcer. However, it is often very hard to find evidence of an existing ulcer, even when the stomach and duodenum are exposed at operation. After the abdomen has been opened, and before doing any gastric surgery, a thorough general intra-abdominal examination should be made for other pathology, such as disease of the appendix or gall-bladder, especially when the presence of a definite ulcer is in doubt.

W. J. Mayo, in 1922, gives the operative results at the Mayo Clinic, as follows: Ninety-five per cent of duodenal ulcers are treated satisfactorily by surgery, 1 or 2 per cent requiring secondary operation. The operative mortality for duodenal ulcer is less than 2 per cent. In gastric ulcer, satisfactory results are obtained by a single operation in 85 per cent. By secondary operation the surgically satisfactory results are increased to above 90 per cent. The average operative mortality in gastric ulcer is about 3.5 per cent. Of the surgical failures, 50 per cent obtain satisfactory results by post-operative medical treatment, and the other 50 per cent he classifies as due to faulty mechanics requiring secondary corrective surgical procedures.

Gastro-jejunal ulcer is a complication which occurs in from 1 to 3 per cent of all gastro-enterostomies. The location of the ulcer may be on the suture line or in the jejunum near the stoma. The cause of the formation of these ulcers following gastro-enterostomy is still unsettled. They have generally been ascribed to errors in technique. The use of silk or linen sutures and the production of a hematoma by needle-pricks, clamps, or finger-bruising is to be avoided. Oschner believes these ulcers may be caused by placing the stoma at a place other than the most dependant portion of the stomach. However, these ulcers occur in the practice of surgeons whose technique cannot be questioned. W. J. Mayo treats jejunal ulcer following gastro-enterostomy by disconnecting the gastro-enterostomy and doing a Finney pyloroplasty.

Obstruction of the pylorus may be an end-result of ulcer. Ulcers located in the pyloric region, duodenal or gastric, may produce narrowing by cicatricial contraction, by inflammatory infiltration of the walls, by reflex spasm from irritation of the hyper-sensitive ulcer, or by adhesions, resulting from pyloritis or perigastritis, which may cause bends or kinks. Most writers agree that operation is imperative when an organic stenosis is recognized clinically. Vomiting and other signs of stenosis, due to pylorospasm and inflammatory swelling associated with an unhealed ulcer, must be differentiated. The hyperfunction caused by organic stenosis ultimately ends in atrophy of the mucosa and in decreased motility. This decrease in motility is followed by gas-

tric dilatation. When gastric atony is present, the operation becomes more dangerous and convalescence will be prolonged. The power of recuperation of the individual has a definite relation to the age of the stenosis. One surgeon had thirty-six patients with stenosis sent to him for operation by two internists who believed in early surgical interference. In these thirty-six there was only one death, a mortality of 2.8 per cent. Twenty-four cases sent to this same surgeon, by other physicians who had temporized, were operated upon with nine deaths, or a mortality of 37 per cent. Gastro-enterostomy gives the best results in these cases of organic stenosis. It is the only procedure that can always be resorted to, no matter how marked the induration of the lesion or how extensive the peripyloric inflammatory process may be. The advantages claimed by some surgeons for pyloroplasty, gastro-duodenostomy, and pylorotomy are clearly counterbalanced by the rapidity of execution and the lesser danger from gastro-enterostomy. When malignant degeneration is suspected, then excision of the ulcer, combined with one of the plastic methods, should be done. Statistics show that 78 per cent of gastro-enterostomies for cicatricial pyloric stenosis have resulted in permanent cure; 16.5 per cent of the patients show marked improvement, being able to return to their usual mode of life, although requiring a more or less strict diet and some medical care; and 5.5 per cent show no remote benefit from the operation.

Hour-glass stomach often is the end-result of an ulcer which has been active over a long period of time. The great majority of these ulcers are situated on the lesser curvature or on the posterior wall. X-ray findings have verified the view that after the ulcer has perforated there is often a tendency to heal spontaneously, and it is in this effort at healing that contraction takes place. Contraction usually takes place in the transverse direction and at the expense of the greater curvature. Because of the extensive scar tissue and perigastric adhesions, the type of operation must be mechanically adapted to the situation and to the recuperative powers of the patient.

Hemorrhage is a frequent symptom of ulcer. It occurs in about 25 per cent of cases. Hyperacute hematemesis may occur in an acute ulcer or during the course of a chronic ulcer. Extensive hemorrhage is best treated by rest and medication. We have two valuable remedies in thromboplastin and in sodium citrate used intramuscularly. Surgeons generally maintain that serious repeated hemorrhage is a definite indication for operation. Gastro-enterostomy is the operation of election, either alone or combined with the use of the Balfour cautery when the ulcer can be definitely located. By gastro-enterostomy distention is overcome, allowing the musculature of the stomach to contract. The condition of the patient is usually such that any more prolonged procedure is contra-indicated. In a case of serious hemorrhage, Bevan has advised a jejunostomy for the purpose of placing the stomach and duodenum completely at rest. Chronic hemorrhage should invariably raise the suspicion of gastric carcinoma or malignant transformation of an ulcer. The treatment

of choice in a case of suspected malignancy is resection.

Perforation is the most fatal complication of peptic ulcer. In the majority of cases perforation overtakes the patient in apparently perfect health. The diagnosis of the resulting peritonitis is easy, but an etiological diagnosis is often impossible. A differential diagnosis between a perforated gastric ulcer, appendicitis, and gall-bladder disease may be difficult; surprises at operation are not rare. All writers agree that operation is urgent; the results are infinitely better when operation is done within the first twelve hours. In the great majority of cases perforation produces collapse, probably due to reflex action. When the patient is examined at this time, the general condition will be found to be serious. The pulse is rapid and weak, respiration is superficial, the expression is one of distress, and the patient complains of severe abdominal pain, usually high up, although not invariably so, with other symptoms of peritonitis. This is the stage of shock, and is not a good time to operate. It is followed by a period of fallacious improvement which has been the cause of numerous mistakes in diagnosis and the loss of very valuable time. The period of remission is the time to operate successfully, and it usually lasts only a few hours. During this time the danger of peritonitis is slight, because usually a very small amount of gastric content has escaped into the peritoneal cavity. This period of remission is followed by the earlier disquieting symptoms. The face is sunken, pain becomes more and more acute, vomiting begins, the pulse is weak, and the signs of peritonitis are fully established. The pain is now often referred to the ileocecal region and is, therefore, mistaken for evidence of acute appendicitis. The purpose of the operation is to treat the peritonitis, as well as the ulcer with its perforation. Murphy stated that in case of peritonitis one should get into and get out of the peritoneal cavity as quickly as possible. This precept should be followed to the letter if possible. Closure of the perforation should be done as well as is possible, considering the very friable nature of the ulcer edges, to be reinforced by a piece of omental graft. If the perforation is at or near the pylorus, with a partial stenosis already existing which would be exaggerated by the sutures used in closing the perforation, a gastro-enterostomy is indispensable, unless a pyloroplasty is performed, following the method of Dr. H. H. Sherk. If the perforation is located on the anterior wall, simple suture alone will suffice. No extensive cleansing of the peritoneal cavity should be attempted. The peritonitis should be treated by drainage, local and suprapubic, by Fowler's position, and by saline injections.

CONCLUSIONS

Recent ulcers should be treated medically, and all other types of ulcer should be given the benefit of thorough medical treatment until cure or chronicity is established.

After failure of medical treatment, surgical interference should be resorted to without delay.

After convalescing from the operation, the patient

should be turned over to the physician for management.

The successful treatment of peptic ulcer requires the combined judgment of the physician and the surgeon.

414 Security Building.

DISCUSSION

W. B. COFFEY, M. D. (Medical Building, San Francisco)—My experience with the surgical treatment of peptic ulcer is that all patients with chronic indurated gastric ulcers should come to operation, and all those with duodenal ulcer should be studied by the physician for a trial period of two or three weeks, unless there are indications for immediate surgical intervention, like unusual hemorrhage, perforation or stoppage of the outlet of the stomach, evidently progressive, and recurrences of pain and bleeding, in spite of proper hygiene and diet.

Even retention of half a barium meal at the end of six hours should not be a signal for surgery, unless ten to fifteen days' trial of rest in bed and Lenhart diet have shown no change in the degree of retention. Many times the conservative course has shown that, as the ulcer heals, the retention is overcome and operation is unnecessary. When patients with recurrent history, whose ulcers break down in spite of proper living and careful observance of instructions, return a second time, surgery is considered at once, but is not carried out until it is demonstrated that there are no etiological factors likely to cause a recurrence.

Even the finding of occult blood for more than two weeks' treatment is not always indicative of the demand for surgery, as a number of cases have shown, where other factors made surgery undesirable. We have had to transfuse some cases, as many as three times before surgery was done, because of the failure of transfusion to stop hemorrhage or even slow oozing. I cannot wholly agree with the writer that there is a wide difference of opinion between good physicians and good surgeons, for the most satisfactory cases on which to operate are those in which the medical study has shown complications of a nature not to be relieved by medical treatment. Practical experience guides one to recognize the medical and surgical type of duodenal ulcer. "If the surgeon can cure 85 per cent of the medical failures, there seems to be no good reason for rivalry." All gastric ulcers are essentially surgical. Adhesions to the gall-bladder, low-grade pancreatitis, pain and retention, all make the type of complications which invite surgery.

One thing more, and that concerns the Sippy diet, which is open to two criticisms. Gastric lavage is not often necessary in ulcer therapy, and is not used in one per cent of our cases, and the use of soda and alkalis generally is absolutely unnecessary and pernicious as a routine measure. It is a poor and dangerous substitute for a proper diet which will regulate and provide for the acidity which is so frequent a symptom. Disguising pain is a doubtful method of treatment always, although at times justified.

FREDERICK A. SPEIK, M. D. (Auditorium Building, Los Angeles)—Dr. Breyer has hit the nail on the head. The physician and the surgeon should get together. There are cases which are amenable to medical treatment, and there are cases that need surgery. It is indeed very necessary that a most careful and painstaking examination should be made and backed by proper judgment.

In seventeen years of experience in this work, I feel qualified to say that the Sippy treatment is not merely giving milk and cream and powders, but that the treatment begins when the patient enters the office. We must not only diagnose whether or not an ulcer is present, but where it is located, how old it is, what complications are present.

When this is done we know what to do with the ulcer, i. e., treat it surgically or medically.

DOCTOR BREYER (closing)—The surgeon is apt to operate too quickly on his ulcer patient, and the physician is prone to hang onto them too long. By greater co-operation I believe this tendency will disappear.

I believe it is far safer to do gastric or duodenal surgery upon a patient who has been under preliminary

medical management, with rest in bed. The local condition of his ulcer will be better, and his general condition will be improved.

I think it is now generally conceded that all patients with chronic, indurated gastric ulcers should be treated surgically. However, gastro-enterostomy alone will cure only a small percentage of them. The radical resections should be reserved for those patients where the indications justify the risk of radical treatment. The last word in gastric surgery has not been said.

It is well to bear in mind the high percentage of cures achieved by well-established methods. By improving our technique, as well as by more carefully selecting our cases, we can still further increase this percentage.

AREA CHANGES IN HEARTS SHOWING DECOMPENSATION AND LOWERED CARDIAC RESERVE, WITH RE- PORT OF TWENTY CASES

By DONALD J. FRICK, M. D., ROBERT H. KENNICOTT, M. D.,
ROLLA G. KARSHNER, M. D., Los Angeles

Cardiac areas, as computed in the orthodiagram, show a fluctuation during compensation and decompensation.

In cases of lowered cardiac reserve, enlarged hearts are seen to decrease in size with clinical improvement.

In a small number of cases, subsequent enlargement of cardiac area accompanying clinical improvement and resumption of exercise would point to cardiac hypertrophy.

Correlation of cardiac areas and clinical findings give information valuable in determining treatment and indicating prognosis.

DISCUSSION by F. F. Gundrum, Sacramento; William J. Kerr, San Francisco; A. W. Hewlett, San Francisco; Harry Spiro, San Francisco; F. R. Nuzum, Santa Barbara.

THE diversity of opinion regarding the variation in heart size, which accompanies changes in compensation, has largely resulted from statements based on inexact data. We have attempted in this paper to so correlate clinical observations and laboratory findings that a clear vision of the subject may be attained. For some time we have felt convinced that the heart area does alter with changes in cardiac function. With this in view, we have selected twenty cases of enlarged hearts, without reference to their outcome, and demanding only that sufficient study had been made upon them to show what, if any, change had taken place during the course of disease. The minimum time of observation of these cases was two months. The maximum was five years and five months. The average period of observation was one year and five months.

Of these twenty cases, eleven showed clinical signs of decompensation at some time during observation. The remaining nine cases showed evidence of lowered cardiac reserve, but no symptoms of decompensation. We here determine decompensation by the clinical signs of venous stasis. In those cases classified under the heading of lowered cardiac reserve, anginal pain and shortness of breath on exertion were the most frequent symptoms.

The cardiac areas were computed from orthodiagrams after the method of Van Zwaluwenburg. Here the formula for computing the area of an ellipse was utilized; namely, the product of the long diameter drawn through the center of the figure and the short diameter erected perpendicular thereto at the widest portion multiplied by the factor 0.7854. Van Zwaluwenburg demonstrated the accuracy of this method by a comparison of areas determined by this method and by planimeter readings. More re-

cently, Karshner and Kennicott, after a study of one hundred normal and abnormal cases, showed an average variation of 2.6 per cent between areas determined by planimeter readings and those figured on a basis of the formula of Van Zwaluwenburg.

Using this very accurate method of measurement of heart areas as a standard, we have demonstrated in seven of the eleven cases of cardiac decompensation a definite decrease in area accompanying re-establishment of compensation. Two of these eleven cases showed progressive increase in size as the hearts gradually failed. One heart showed no change with clinical improvement, and one increased in area.

Of the nine cases of lowered cardiac reserve with cardiac enlargement, five showed decreased heart areas upon clinical improvement; three remained unchanged; while the one remaining heart increased in area as cardiac reserve improved.

In fourteen of the twenty cases, a change in heart area was demonstrated, while four remained unchanged and two increased in size with clinical improvement.

In the entire series, four cases at some time showed increase in heart areas accompanying clinical improvement. These probably demonstrate the result of muscular hypertrophy. The improved tone of the heart is readily observed during fluoroscopic study. The complete orthodiagrammatic report in such cases throws more light on the reason for the increased size than a simple statement of area in percentage would indicate. Even among those cases of cardiac decompensation where a definite decrease in cardiac size has followed compensation, there are a few cases which have shown a progressive increase in size upon a resumption of activity following treatment with rest. The area in these cases never reaches the height reached during the period of decompensation, and the tone of the muscle observed during examination shows progressive improvement.

The accompanying chart shows in detail, under the date of examination, the diagnosis, etiology, electrocardiographic and polygraphic diagnosis, orthodiagrammatic findings, and clinical observations in the twenty cases studied.

The diameters M. R. and M. L. and total diameters are included, since they are the ones commonly employed by the clinician in his study of the heart. These measurements give information of comparative value, but fall far short of measurements of cardiac area as a means of studying changes in the size of the heart.

The first diagram represents the orthodiagrammatic findings of a normal heart. In computing cardiac areas, the long diameter A. B. (in centimeters) is multiplied by the short diameter C. D. (in centimeters), and the product thus obtained is divided by the normal obtained in a similar manner based on body weight. The perpendicular line represents the anatomical center of the body. The M. R. and M. L. are raised perpendicular to this central line at the point of greatest cardiac width to the right and left.

The diagrams were prepared by making a composite picture of the actual orthodiagrams. They demonstrate the changes in the cardiac silhouette

CASE 22445

CASE 22361

CASE 2541

CASE - 1939

during the course of disease. The areas computed as described above are recorded at the base of the outline in each case.

Case No. 2541—This patient was a housewife of 50. She reported September 29, 1919, complaining of dyspnoea and orthopnoea of two weeks' duration. With the exception of repeated attacks of tonsillitis and typhoid fever at the age of 34, the patient had been in good health until February of 1918, when she noted a sudden irregularity of her heart. Physical examination revealed a mitral insufficiency and stenosis with an auricular fibrillation. Her orthodiagram at this time (September, 1919) showed an area of 162 per cent, and is represented by the outer solid line in the diagram. By November 17, 1919, the patient had improved; her pulse, still irregular, was slowed and no longer showed a deficit. Her total transverse diameter was reduced 2.5 cm., and her cardiac area reduced 49 per cent (represented by the heavy, broken line). On December 23, 1919, the patient again reported, showing signs of decompensation; her cardiac area had increased to 133 per cent, shown by the small, broken line on the slide. By March 29, 1920, the patient was greatly improved, her heart had receded to its previous area of 116 per cent, which is virtually that of November of 1919, and shown as the heavy, broken line.

Case No. 1939 is one of a physician of 58. The diagnosis was luetic aortitis, cardiac dilatation and hypertrophy, chronic nephritis with hypertension, and chronic myocarditis. He presented a right bundle branch block. He had repeated attacks of pulmonary oedema, finally dying in one in January, 1924. He was first seen in March, 1917. He gave a history of having had two attacks of acute oedema of the lungs in January and March. He was complaining of dyspnoea on exertion. He had a blood pressure of 210 systolic and 165 diastolic. His blood Wassermann was three plus. After being on anti-luetic treatment, he reported much improved on June 26, 1917.

His first orthodiagram made in February, 1920, gave an area of 120 per cent (represented by the inner broken line), and his fluoroscopic examination revealed a uniformly broad aortic shadow 6 cm. wide. He was feeling well, and working at this time. His antiluetic treatment was continued. January, 1922, patient reported at office. He was definitely failing in health. His electrocardiograms showed ventricular extrasystole with right bundle branch block. His cardiac area had increased to 138 per cent (represented by the outer solid line), an increase of 18 per cent. In December, 1922, he had a severe attack of hemorrhagic oedema of the lungs. The patient grew progressively worse and died in January, 1924, with acute hemorrhagic oedema of the lungs.

Case No. 22,445—A nurse, aged 51, came to the office in August of 1919, complaining of "heart trouble." Her previous illnesses were scarlet fever, tonsillitis, typhoid fever, malaria, and rheumatism. A diagnosis was made of mitral and aortic insufficiency, chronic myocarditis, and auricular fibrillation. In September of that year her heart was compensated. Her cardiac area was 180 per cent (inner dotted line). She was on duty as a nurse. In September, 1922, she was suffering from decompensation, with ascites, oedema of legs, cyanosis, and enlarged liver. Her cardiac area was 252 per cent of the normal (the broad, broken line). The patient was improved by February, 1923, but never regained her compensation. Hers was a history of steady decline. When last seen, in January of 1924, she was able to get about a little, but was greatly restricted as compared with her former activities. Her cardiac area was 309 per cent, and is shown in the diagram by the solid line.

Case No. 22,361—A man of 42, first seen in July, 1919, complaining of cough, dyspnoea (nocturnal, and on exertion), and precordial pain. He had a decompensated heart, with mitral regurgitation and chronic myocarditis. His cardiac area was 191 per cent. In October, 1922, after

treatment, the patient was free from symptoms and presented a cardiac area of 165 per cent. Improvement continued and the patient was allowed limited activity and four hours' work at his office daily. His electrocardiograms were negative but for ventricular extrasystoles. In May, 1923, his heart was slightly larger (168 per cent), but of definitely better tone. This heart outline is represented by the broken line in the illustration. When last seen in February, 1924, the patient was free from signs of decompensation. He had slight dyspnoea on exertion. He was active about twelve hours a day, with two hours' rest in the afternoon. His heart was definitely larger than at the previous examination (185 per cent), but his muscle tone was good.

CONCLUSIONS

1. That cardiac areas, as computed in the orthodiagram, show a fluctuation during compensation and decompensation.
2. That in cases of lowered cardiac reserve enlarged hearts are seen to decrease in size with clinical improvement.
3. That in a small number of cases subsequent enlargement of cardiac area accompanying clinical improvement and resumption of exercise would point to cardiac hypertrophy.
4. That correlation of cardiac areas and clinical findings give information valuable in determining treatment and indicating prognosis.

1136 West Sixth Street.

DISCUSSION

F. F. GUNDRUM, M. D. (Capital National Bank Building, Sacramento)—I have been very pleased with this paper. The publication of such accurate, painstaking, and continuous study of heart size will throw a very needed light upon our hitherto somewhat hazy concepts of the relation of cardiac dimensions to cardiac ability. We have long been taught that heart weakness was associated with dilatation, and I believe it was Osler who said that endurance was to be measured by the ability of the heart to resist this constant tendency to dilate. With more accurate study, as appears in Dr. Frick's paper and elsewhere, it begins to seem evident that this idea will have to be somewhat revised, and endurance may prove to be, in large measure, a function of blood-sugar. Although we are all daily seeing examples of the reduction in the width of cardiac dullness which accompanies the recovery from heart failure, increase in the ability of the heart to do work is not always associated with a decrease in heart size. It is hardly necessary to use such elaborate technique to make a clinical diagnosis of heart failure, and to get a quite accurate picture of the general outline of the heart. However, this sort of research will prove invaluable in giving us the exact relations between those very small differences in heart size and shape (if there are any) which are associated with the minor degrees of heart insufficiency, and perhaps foretell a cardiac breakdown.

WILLIAM J. KERR, M. D. (University Hospital, San Francisco)—The report by Drs. Frick, Kennicott, and Karshner is of interest to physicians in general and to cardiologists in particular, because it emphasizes the value of accurate methods of determining cardiac measurements. We cannot rely on our present methods of physical examination for the accurate sizes of hearts, particularly in those cases where emphysema is a complication or in individuals who have an unusual amount of subcutaneous fat. Here the orthodiagraphic method comes into use.

The authors have shown the variation in cardiac area over a long period of time in their series of cases, and their charts definitely show that the variations are usually associated with changes in the cardiovascular status of the patient. The value of this method in treatment and in prognosis seems to me to be very great and should be more generally employed. One should be extremely careful, I think, to have the orthodiagrams taken of the patient in the same position each time so that changes in shape and position of the heart by changes and position in the patient will be obviated or minimized.

I feel that the study of the heart with the area of the orthodiagraphic shadow and the orthodiagraphic plate be-

fore us for changes in contour give a very good idea of the conditions present, and is much more satisfactory than either method alone. These methods do not replace the other methods of physical diagnosis and examination of the patient, but are useful aids in the proper treatment and prognosis of the case.

A. W. HEWLETT, M. D. (Stanford University Medical School, San Francisco)—This paper demonstrates the value of accurately measuring the size of the heart shadow by means of the x-ray. The difficulty encountered in making accurate measurements of the heart shadows in different patients arises from the considerable variations encountered in normal persons. On account of these variations, the heart shadow must be considerably larger than the average before we are certain that it exceeds the upper limit of normal. In the present paper, comparative observations were made on the same individuals at different times, so that small changes in area are significant. These comparative measurements show clearly that, in certain patients, the heart shadow lessens as compensation improves. From my own experience with chest plates of cardiac patients, I can confirm the observation that certain patients show a decrease in the heart shadow coincident with clinical improvement, while others show little or no change. The authors report four cases in which, at some time, the heart shadow became larger during clinical improvement. They attribute this to cardiac hypertrophy. It appears to me improbable that a marked change, such as that observed in Case 1285, could be due entirely to thickening of the heart muscle. Increase of the heart shadow, especially in diastole, may be caused by a slower heart rate. It is also probable that, in some instances, hypertrophy goes hand in hand with a moderate dilatation even when compensation is improving.

HARRY SPIRO, M. D. (Flood Building, San Francisco)—The orthodiagraphic method of cardiac examination has had a hard path to travel. Popular prejudice decided that the method was too tedious, required extraordinary skill and high-priced and complicated apparatus; therefore, it has not been more in demand. But no sooner does an individual decide upon a careful and thorough study of cardiac conditions than he realizes that, for dependable work, orthodiagrams are an indispensable supplement to the radiograms.

Today the orthodiagraphic apparatus is very simple and does not demand more than ordinary skill to operate and interpret. Its value is tremendous, particularly as an aid in diagnosing borderline cases of cardiac defects. The authors have shown further that it may be a factor in preventing a cardiac breakdown because one can recognize changes in size and shape of the heart which often precede cardinal symptoms of severe cardiac distress.

While in general I do not believe that cardiac shape is dependable in judging cardiac muscle tone, still there are cardiac types which are reliably associated with certain cardiac defects. For instance, if an orthodiagraphic study has shown a certain type heart, and after a period of time investigation shows a distinct deviation from the type previously found, one could reasonably assume that the heart was not standing up to its work properly, and the treatment should be changed accordingly.

We have always believed that progressive increase in cardiac size spelled approaching trouble. On the contrary, the authors have called attention to the possibility that if a decompensated heart improves and decreases in size, and subsequently as the improvement continues, the heart is shown by careful measurements to be increased in size; then this latter increase in size is due to healthy changes and need not be feared. The proof of the above is definitely a step forward, and shows with what thoughtful judgment the authors performed their work and illustrates forcibly the great value of orthodiagraphic study.

Drs. Frick, Kennicott, and Karshner are to be congratulated in their work of blasting another stone from the path of orthodiagraphy and scoring another point for the long neglected, but faithful, hard-working heart.

FRANKLIN R. NUZUM, M. D. (Cottage Hospital, Santa Barbara)—This paper demonstrates in a very convincing manner the aid that is available by the use of accurate methods of determining the size and shape of the heart. The point has been established that the size and shape of the heart varies in the period of time that elapses between broken compensation and compensation, and that a knowl-

edge of this change is of value in diagnosis, prognosis, and treatment.

Quite aside from the object of this paper, the change of the size of the heart as a result of disease, are some observations made recently in Boston upon the change in the size of the heart in trained athletes following severe exertion. The same methods of determining heart measurements were used, and the information gained is very interesting. Heart measurements were made of these athletes before, immediately after and some days after the completion of a 25-mile marathon race. This race, being an annual event, attracts the best distance runners in the country and men who are thoroughly trained for the event. In brief, the width of these hearts decreased an average of 2 cm., as shown by measurements at the conclusion of the race. Within two to five days these hearts had again returned to the size as demonstrated before the race. This is not in harmony with what many believed would happen as the result of a severe strain such as this race must be. It demonstrates again the value of accurate methods in establishing facts.

The Clinical Teacher and the Medical Curriculum—Harvey Cushing, Boston (Journal A. M. A.), says there are fashions in teaching, like fashions in other things, and one must conform or be regarded as out of date, even though, after all, we may reach our destination whether we ride side-saddle or ride astride. Just now, for example, in our medical schools the "didactic lecture" is taboo. Who first put the taboo on lecturing was probably someone in authority incapable of holding the attention of a group of students by this method. Individuality is now submerged: our teaching, must—to use a greatly abused word—be standardized, as though our schools were factories. The personal influence of the teacher has largely become swamped, and we try vainly to atone for this by juggling with the curriculum, forgetful that no two instructors in any two schools can possibly reach students with precisely the same methods; and that no two students get their inspiration, such as it is, in the same way out of their particular school or its individual instructors. I presume the Harvard Medical School is no different from most medical schools, in that no faculty member is quite satisfied with the existing curriculum and, as a result, about every three years some one protests with sufficient energy to force on his reluctant colleagues some radical changes. Students can be well grounded through the medium of any course. In any old and established school, the curriculum inevitably becomes hidebound. Meanwhile, we have become fairly well accustomed to the view that subjects beginning with the study of morphology and ending with the clinical specialties must be taught in a given sequence. So far as the curriculum is concerned, our discussions in faculty meeting are given over largely to the struggle for elbow-room between established courses, of which there are too many. We have just been going through one of our triennial turn-overs at the Harvard Medical School, in the endeavor to find out what is wrong with the student and with our method of teaching. This time, pressure has been brought to bear by certain members of the faculty of a philosophical turn of mind, who have discovered that the trouble with the undergraduate is that he has no time for intellectual cogitation. Consequently, at the risk of not meeting our obligations to state board requirements, we have materially cut down our hours of instruction so that the students have their freedom Tuesday afternoon and Thursday afternoon and all day Saturday and Sunday. We have as yet made no statistical study of the amount of rumination they do in these free hours; nor do I think such a study will ever be made, because by the time there are sufficient data to rely on we shall probably have gone back to the old system, or new courses will have crept in to fill up these free afternoons.

EDITORIALS

RULES AND FEE SCHEDULE OF DISTRICT OF COLUMBIA MEDICAL ASSOCIATION PLEASE ORGANIZED LABOR

The reaction produced by the new published rules and fee schedule of the District of Columbia Medical Association still reverberates through the daily and periodic press of the country. Many editors constantly criticize the action, while others, and particularly that part of the press identified with organized labor, are pleased at the action taken. The majority of commentators profess to see in the action a "tightening up" of physicians' organizations and the introduction of "business ethics" into their methods and conduct. Some editors castigate the doctors for introducing the "lockout" and a scale of wages and working conditions similar to those of labor unions. Editors of papers sympathetic to labor unions welcome these innovations and predict affiliation of medical associations with the American Federation of Labor as the logical end to this movement.

Fee Schedule—The fee schedule is too long to reproduce. Fees vary from \$3 to \$5000 and upwards. The rules relating to fees are interesting. They are:

1. The following fees shall be charged for professional services, subject, however, to the several rules which are appended: . . .

2. The foregoing table contains the standard fees which *shall be demanded*; they shall be *increased* according to the judgment of the practitioner concerned, in all cases of extraordinary detention or attendance; also in proportion to the importance of the case, of the responsibility attached to it, and to the service rendered when these are extraordinary. They shall be *diminished* at the discretion of the physician when he believes that the patient cannot afford to pay the regular fees, and yet is able to make some compensation; but diminishing the fees except for motives of charity and benevolence is a violation of this regulation.

3. Medical officers connected with the staffs of the hospitals and dispensaries in the District of Columbia shall charge the usual fees for medical services rendered to persons who seek gratuitous services when they are able to pay.

4. Clergymen are not entitled to gratuitous services except when they are in indigent circumstances. Graduates of medicine are not entitled to gratuitous services unless they devote their entire time to the practice of medicine or by reason of age or infirmity have retired from the regular practice of medicine, or unless such graduates of medicine are in indigent circumstances.

5. It is not designed by these regulations to prevent gratuitous services to those who are incapable of making remuneration without distressing themselves or their families.

6. When a physician engaged to attend a case of obstetrics is absent and a second attends the patient, the latter may charge the full fee, but shall relinquish the patient to the first on his return; and in no case shall the second continue to attend except to render indispensable service during the continued absence or disability of the first.

7. When one or more physicians are called in consultation the attending and consulting physician or physicians shall charge at least the ordinary fee for delivery or other services; but when the latter are not detained in attendance they shall only charge the usual fee for consultation.

8. It is recommended that the members of this society

present their accounts for professional services at the close of the attendance; and it shall be the duty of each member to obtain, if possible, a monthly settlement from all his patients.

9. No member of this society shall make a contract, expressed or implied, to attend an individual, family, club, lodge, or other organization by the year, or on any terms other than those authorized by these regulations.

Rule 9 apparently would prevent membership of any salaried doctor, regardless of the size of the salary or the nature of his work.

OTHER RULES

In addition to those affecting fees, there are other interesting rules, from which we quote:

2. In certificates of illness concerning absence from official duties given to employes in the public service, or others, the disease shall not be specified, neither shall the name or nature of the disease be divulged by any written description or statement of symptoms, given to the patient, nor by any specification of the disorder, nor by any disclosure which may be construed as an evasion of the purpose of this regulation.

3. It shall be the duty of members of this society to discourage patients from defrauding other members, and it is expected that the members will use all just and proper means to assist one another in the collection of their fees for professional services.

4. No member of this society who has been called in as consulting physician, in a medical or surgical case, shall assume sole charge of the patient, during the same illness, unless he shall have been specifically requested to do so by the attending physician.

5. No member of this society shall offer, solicit, give, or receive any commission for recommending or referring patients for general or special treatment, diagnosis or operation; or shall solicit or accept any commission from any pharmacist or other dealer in supplies and appliances for the sick and injured on account of patients referred to them.

1. Every institution for medical charity shall require from every applicant for relief in its hospital or dispensary a written certificate, to be obtained as hereinafter provided, that said applicant is unable to pay. Emergency cases are to be excepted from the operation of this rule.

3. Members of this society shall be entitled to the privilege of attending private patients occupying private rooms in any of the public hospitals of this city.

4. The members of the medical staffs of hospitals, when attending medical or surgical cases in private pay rooms, shall insist upon proper payment for their services, except in the case of patients who are unable to pay.

5. Whenever the medical staff of a hospital or dispensary, or any member thereof, is forced to resign, and when, after due hearing, this society finds that the resignations were for unjust and insufficient cause, it shall be forbidden to any member of this society to accept a position on the staff of said hospital or dispensary.

This presumably is the rule referred to by some as the "lockout rule."

6. Whenever one or more members of the medical staff of a hospital or dispensary are dismissed, and when, after due investigation, this society finds that such dismissal was without just and sufficient cause, it shall be forbidden to any member of this society to fill the vacancy created thereby.

9. No member of the staff of any hospital, receiving patients in private rooms, shall attend such private patient sent to the hospital by a member of the society not a member of the staff, unless specifically requested to do so by the attending physician.

It is not our purpose to comment upon the action of the Washington physicians, but rather to review the parts of their action that have led to so much controversy.

GROUP MEDICINE UNDER A NEW NAME

Under the new and particularly inappropriate name of "Guidance Clinics," group medicine has again come to the fore: by group medicine, meaning grouped service by one or as many physicians and other persons as are necessary to make complete and inclusive diagnoses and render any and all indicated services to any individual person.

In the beginning, the old-time family physician was the "group," the "health center," the "child guidance" clinic. He included in his sphere all of the best knowledge then available in the supervision, advice and care he gave to his clients. Most of them still continue to render to the best of their ability all the broad services that some appear to believe to be newly discovered by them. They have guided, and are now guiding, some pretty fine specimens of children to manhood, and then they keep on guiding them until death calls.

Then knowledge increased and became more complex, and medicine, in the broad sense of that term, also became more difficult and complex. Most doctors tried to keep up with and utilize the best of that knowledge in the "guidance" of their clients. Most of them still do so.

Medical schools tried to sort theory from facts and add what was worth while to the instruction given to crop after crop of younger physicians produced annually. They still do precisely this up to a certain level of attainment, and above that level both education and practice have split the field into several essential specialties. Also some that probably are unessential. Practice and education have both then tried to co-ordinate these specialties so as to bring them to bear upon the individual in diagnosis, treatment and "guidance." Many schemes for doing this have been promoted, including clinics, health centers, partnerships, groups and others, and now we have the latest, the "Child Guidance Clinic." Tomorrow it will be some other name.

Yesteryear Doctor A practiced medicine, including "guidance" for child and adult. Last week Doctors A, B, and C formed a partnership to expand their service. Yesterday Doctors A, B, C, D, E, plus pathologist, psychologist, nurse, social worker, and others formed "groups" and corporations to do this work. Today Doctors A, B, C, etc., form a clinic, a health center, a service station, a life-prolonging clinic, a "guidance clinic," or some other form of wholesaling health service "free." Tomorrow the popular name will again change to the latest fad in nomenclature; but you will notice that all through the past, today and tomorrow, the service-givers are the same people. Will they do better work under one name than another?

On page 164, this issue, is a well-told advocacy of "Child Guidance Clinics" by Doctor R. L. Richards. It is a clear and worthwhile presentation of an old subject under a new and unfortunate term. It is an excellent health and happiness "Bill of Rights" of citizens similar to what one will find in the writings and, to a surprising degree, in the practices of the Weir Mitchells, Oliver Wendell Holmes and Oslers of other generations. In a word, it is an excellent restatement of an ideal that intelligent and service-loving people always have been, and

are now striving for, not only in the broad field of health, but in other fields of good citizenship. If there is a single item in this "Bill of Health-rights"—so-called "guidance" service—that every worthwhile physician is not doing his best, either as Doctor A working alone or as Doctors A, B, C and others working in groups, to bring about, we would like to know what it is.

Another indication that "Child Guidance Clinic" is a slogan rather than a new movement—except in one particular to be presently noticed—is in the fact that scores of Doctors A, B, C's, who previously worked under some other designation, are now coming out under the—for the movement—popular title of "guidance clinic." There will be several of them in California within a year or so, and in a few more years they will be forgotten or the same worthy ideal will be again resloganized.

There is one feature of the much-promoted "guidance clinic" movement which seems to constitute its chief motivating force, as it does so many "new" movements in health. It is, that it must spring full-panoplied as a wholesale measure under government or some national (usually non-medical) organization control and direction. Our Doctors A, B, C must, for the time being, metamorphose themselves over night into new beings with vastly increased wisdom and powers of leadership under government or some other wealthy and not too inquisitive body. In other words, the promotion of things medical and social now follows something of the same channels used in promoting a new breakfast food or a new patent medicine. The essential feature of such promotion is salesmanship, which, if well enough managed and well enough financed, will create a desire for anything.

The paper by Doctor Rosanoff (page 167, this issue) illustrates more in detail the working of the movement for "child guidance" on a large scale. *One of the chief points in this movement is that all services to all people, regardless of their financial situation, are free of direct cost to the patient.* The very large costs connected with this service are noted by Doctor Rosanoff, as well as the *present* method of meeting these costs.

Doctor Rosanoff himself, an earnest advocate of this group method of practice, says: "The clinic procedure contains nothing that is new to mental science, except perhaps as it involves a more complete organization for the carrying out of all that we know has to be done."

LOS ANGELES AND THE PLAGUE

The prompt, scientific and effective methods employed by Los Angeles in stamping out almost at its birth a threatening epidemic of pneumonic plague is a performance highly creditable to that city, and sets an example that might well form a precedent for the guidance of other municipalities in times to come:

"No visitation," says the Arizona Republican editorially, "containing more frightful possibilities ever fell upon an American city. There was never in any plague a higher percentage of fatality, and there was never one more readily communicable. A little ignorance on the part of the authorities, a little hesitation or delay, and there would have been witnessed the most frightful devastation.

"Los Angeles is not resting on its oars since this one

voyage is safely ended. Within a week it has appropriated \$250,000 for a campaign against rats and squirrels; it has passed an ordinance requiring that new construction—and old construction as well—shall be rat-proof; that old buildings to which precautionary measures cannot be applied shall be destroyed.

"There are few cities and towns in America so guarded. We suppose there is no other so worshiped by the people who live in it. Los Angeles is a religion of Angelenos. We have jibed them often for their self-assertiveness and for purloining our Grand Canyon of the Colorado, but, after this, their greatest exhibition of readiness and efficiency, we forgive them all."

And so a great city, by wise and prompt action, converted what gave promise of becoming a calamity into an asset of far-reaching consequences. Although reputed to have an unusually high percentage of anti-medical citizens and to be the home of many kinds of versatile quacks, the city's action in times of serious trouble seems to show that, at most, the quackery is but a thin veneer easily brushed aside to give their educated medical agencies a free hand and generous support.

WHO PAYS THE DEFICIT?

Persons who contribute to the support of the free and part-pay work of hospitals have asked if the hospital rates paid by the State Industrial Insurance organization (state fund) were sufficient to cover the cost of the service rendered to their policyholders, and if not *who pays the deficit?*

This is a pertinent question, the answer to which may be interesting, not only to contributors to private charity, but to other citizens, and particularly to those who are served.

We know of no instance where carriers of industrial insurance operating under the provisions of the Workmen's Compensation Act of California pay hospital rates sufficient to cover the *cost* of the class of service that the injured workman is entitled to under the law.

The airing of this question in another state led promptly to an increase in the rates paid by carriers to at least the *cost of the service to the hospital.*

Additional data are being secured, and we will discuss fully several angles of this most interesting problem and some of the consequences of present practices in an early number of CALIFORNIA AND WESTERN MEDICINE.

OF INTEREST TO OUR CONTRIBUTORS

Now that the 1925 session of the California Medical Association is approaching, it seems advisable to anticipate some of the usual questions and requests made by authors about publication of their essays.

The author of a paper presented before the California Medical Association or any of its sections, *may* offer his paper for publication in CALIFORNIA AND WESTERN MEDICINE, but he is not *required* to do so as was the case prior to three years ago. Likewise, CALIFORNIA AND WESTERN MEDICINE may accept or decline any paper from any source whatsoever. Members who wish to offer their papers to CALIFORNIA AND WESTERN MEDICINE should send them to Emma W. Pope, secretary C. M. A.

and associate editor for California, or to the editor. Receipt will be promptly acknowledged, after which the essay will be carefully examined by members of the Editorial Council and either accepted or declined.

Date of Publication—Except in a few special instances, such as the announcement of new work or invited special contributions, the exact date of publication cannot be foretold. It depends upon too many governing influences, such as the date of receipt of manuscripts, the physical "make-up" of the issue, the "balancing of subjects," the proportional representation—geographical and by specialties—the amount of editorial work required, the length of the paper, and other considerations.

Helpful Suggestions—If it requires more than 3000 words to do justice to a subject, the subject is too broad for a general medical journal. If the essay exceeds 4000 words, it is not acceptable to CALIFORNIA AND WESTERN MEDICINE.

Formal stereotyped "case reports" rarely are read by anyone but the editors, and still more rarely contribute anything to the value of an essay.

Well-made photographs or well-done india ink drawings that really illustrate add value to any paper. Poorly done photographs, roentgenograms, and most "tables" definitely detract from the value of a contribution.

It is well for authors to bear in mind, as the editor is required to do, that CALIFORNIA AND WESTERN MEDICINE is a general medical journal. Probably more than 75 per cent of its readers are in general practice, and the other 25 per cent are divided between more than twenty specialties. Specialists, in preparing their articles for publication, should bear this fact in mind, and submit to CALIFORNIA AND WESTERN MEDICINE those phases of their specialty that ought to be interesting to all physicians. The more limited and more highly technical articles, written primarily for an audience made up of specialists in their subject only, should be submitted to special journals and not to a general medical journal.

Advance copies of papers to be read before the C. M. A. may be submitted at any time. This is particularly desirable for general addresses and the annual addresses of section and other officers. Priority in publication will be accorded to all officers' addresses, addresses of section chairmen and reports of the proceedings of sections, *provided these are submitted to us in good shape promptly*. Carefully prepared reports of the proceedings of sections would be a valuable contribution to medicine if the responsible officers would take the trouble to prepare them for publication.

In all cases, please save trouble, expense, and correspondence by submitting one original, clean, double-spaced typewritten copy on standard letter-size paper, and one carbon. At the same time authors will facilitate the handling of their copy if they will submit the names and addresses of physicians whom they desire to have discuss their papers.

Like all reputable medical journals, CALIFORNIA AND WESTERN MEDICINE will not publish knowingly a paper that has been submitted and accepted

for publication elsewhere. CALIFORNIA AND WESTERN MEDICINE will publish papers declined by other publications, *provided* that, in the opinion of the Editorial Council, they are worthy of publication. However, papers submitted in the first instance to CALIFORNIA AND WESTERN MEDICINE will be given priority over such papers in publication.

No more certain cause of delay in publication can be invented than for an author to criticize his colleagues in his scientific discussion. This also often is the determining point in accepting or declining a paper by the Editorial Council. Those who wish to offer criticism of the profession as a whole or any section of it, should send letters to the editor. If they wish to criticize individual physicians, the letter should go to the secretary of the appropriate county medical society or to the secretary of the California Medical Association.

The paper that secured the widest and most favorable comment of our last year's issues was revised twice by the editors and three times by the author. Incidentally, the author "cussed us out" twice and wrote a fine letter of apology after reading the reviews on his article. The moral is, that an author should no more risk his scientific and cultural standing by sloppy, unedited copy than he would risk his social standing by attending a formal party dressed in overalls. Members of the Editorial Council like to examine clean, double-spaced, original typewritten copy. One of them recently told the editor that he believed that a medical essayist who would send in a smeary, much-interlined carbon copy of his article would operate with dirty fingernails. Perhaps he was joking, but it is well to remember that the only *permanent* background a doctor can create is his written and published word. This should represent the best that is in him.

LIFE INSURANCE WITHOUT MEDICAL EXAMINATION

We have been asked to discuss editorially the significance of the movement among some life insurance companies to do away with medical examinations of their policy-holders. We have no inside information, but certain reasons seem clear and certain consequences may be predicted.

Life insurance is a business; a big business carried out for financial gain and conducted under business ethics. Executives in the field will readily admit that the medical part of their work is the most troublesome and physicians' findings and conclusions the most uncertain element in the business as a business. This undoubtedly is a fact. Even under the most favorable auspices and with the best possible work by the best physicians, the results must be held up alongside careful actuarial tables before money can be assured of its earning.

With all the statistical and actuarial data that have accumulated through the years, it should be about as easy to estimate the hazards of life and thus fix a "safe" premium rate without a medical examination as it is with one. Therefore, when considered purely from an investment standpoint, it undoubtedly would be easy to fix a profitable pre-

mium rate without a medical examination. This rate would, however, perforce be a higher one.

There is another interesting speculation which might be offered. Many of the important insurance companies have developed and are rapidly developing great medical and nursing service departments of their own. By this method they can prolong the lives of their policy-holders by rendering them medical, hospital, nursing and "welfare" service, and they can thus control many situations not otherwise within their power. This substituting a policy-holder's medical service for a pre-policy medical examination suggests possible advantages to the investor. Whether or not it may prove of advantage or disadvantage to the welfare of policy-holders and physicians depends upon how it is to be handled. The possibilities are great in both directions.

There is still a third possible consequence to this movement: Groups of insurance carriers may support some great wholesale medical service that would handle all phases of medical work for their companies. Services of this class are now well established and others are in the making in several places. If wholesale medicine in some form is to come, as appears not impossible, at least for the majority of people, and consequently for the majority of physicians, the battle will be between great private organizations on one side and government on the other. Both are making definite tangible progress clear to anyone who cares to observe.

SUPPLEMENT

As is the editor's custom with editorial matter dealing with important problems of organized medicine, the above editorial was sent in proof form to twenty officers of the California Medical Association for advance comment or criticism. The questions raised by the advisors are all answered in the following reproduced from the Nation's Health, which is well worth careful perusal by all thoughtful physicians:

"The Aetna Life Insurance Company made the surprising announcement in September that thereafter on business examined within two years, additional insurance up to \$10,000 would be issued without medical examination. The Travelers and Connecticut General have been setting aside one month a year during which time this privilege was available to certain limited schedules, so that the principle is not new to the insurance world but, coming as it does within a month from the concession made by the Prudential on Industrial policies in writing twenty-year endowment policies up to \$2000 without medical examination, it is freely interpreted by the insurance press as indicative of a general movement toward unexamined business.

"This does not mean that the insurance to be written is to cover an unselected group, as the privilege is open only to those who have been examined within two years. The requirement of a written statement of health eliminates many bad risks, and an important factor in making the system sound is embodied in the regular health inspection feature. The object, according to Aetna officials, is not to segregate a highly superior group, but to strike the average. The Prudential limits its unexamined business to \$2000 and to endowment insurance, and the additional policies may be written only by agents who have been with the company at least one year. The Aetna accepts even convertible term insurance up to \$10,000.

"In commenting upon the possibilities of final universal acceptance of insurance under the non-medical plan, The National Underwriter says:

"The success with which British and Canadian com-

panies have written unexamined business forecasts a favorable experience. The Sun Life of London started writing unexamined business in 1902, and has improved the status of this class until the cost of insurance is the same to them as to those who have been examined. . . .

"The success of group insurance in the amount of business being written without examination is advanced to show the practicability of insurance without examination. With an inspection report required and reliable agency force, there is no reason why an average group should not be obtained, in the opinion of those advocating the plan.

"A number of states require medical examination, and in these states neither the Aetna nor the Prudential plans can be put into effect. . . .

"Some states require medical examination, even in the case of group insurance, although most of them have waived the requirement on group. In one state where this requirement was made, the group companies made the examinations, but would consider the report as a group and not on individual cases, and if the group as a whole looked satisfactory, those who were undoubtedly impaired and uninsurable on individual policies were acceptable under the group.

"It can probably be predicted that if this practice of writing insurance without examination becomes general that the law will eventually be repealed or waived in all the states. It is probably significant that in New York and Illinois and other states that are noted for the care with which their insurance practices have been protected by law, do not require a medical examination. This seems to carry out the opinion of the critics who say there really is no excuse for the law requiring examinations and that the theory on which the law is passed is faulty."

A DIFFICULT SITUATION CLARIFIED

The question of the control, operation, and personnel of medical laboratories has been a burning one for some years. Upon the recommendation of a joint committee, representing the American Medical Association, the American Chemical Society, and the American Association of Pathologists and Bacteriologists, the House of Delegates of the American Medical Association approved and endorsed the following statement, which ought to settle the matter:

"In proposing the following specific recommendations concerning the regulation of clinical laboratories, the joint committee of the American Medical Association, the American Chemical Society, and the American Association of Pathologists and Bacteriologists wishes to emphasize the importance of encouraging and insuring the adequate education of every laboratory worker in the fundamental sciences which he applies. A clinical laboratory—as that term is used by the committee—is an institution organized for the practical application of one or more of the fundamental sciences by the use of specialized apparatus, equipment and methods for the purpose of ascertaining the presence, progress, and source of disease.

"It is the unanimous judgment of the committee:

1. "That it should be illegal for any person not licensed by law so to do, to assume the responsibility of making the diagnosis or of deciding on the progress or source of disease on the basis of any results of a chemical, pathologic, serologic, bacteriologic, radiologic or microscopic observation or other laboratory examinations undertaken; and that where laws do not now restrict diagnosis or the clinical interpretation of laboratory examinations to licensed classes of medical practitioners, laws should be enacted to effect that end.

2. "That any law providing for the licensing of professional workers in laboratories devoted to ascertaining the presence, progress or source of disease should provide for the examination of members of each profession by competent authorities belonging to the same profession.

3. "That as long as an organization or individual engaged in examinations to ascertain the presence, source or progress of disease refrains from all diagnostic and

prognostic interpretation of the results of such laboratory tests, as provided for in paragraph 1, any effort to force such organization or individual to place itself under the direction of a representative of any other profession is to be deprecated.

4. "That the American Chemical Society, the American Medical Association, and the American Association of Pathologists and Bacteriologists should co-operate to establish the principles enumerated in the foregoing resolution whenever legislation in this field may be proposed, and that the co-operation of other national bodies should be solicited.

5. "That clinical laboratories be standardized in accordance with the principles laid down in the preceding paragraphs, and legislation should be enacted to insure competent personnel and suitable equipment."

CALIFORNIA MEDICAL ASSOCIATION AND THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA

The California Medical Association—The present name of your state association was adopted June 23, 1923, to conform with the spirit of organization.

The Medical Society of the State of California—The former name of your state association, retained by a society voluntarily formed of those members of the C. M. A. who were unwilling to dispense with the services of your legal department when Indemnity and Legal Defense was discontinued as a society undertaking.

Dues—The yearly assessment to each association is \$10. The C. M. A. dues are paid through your county secretary. Optional Medical Defense dues are sent direct to the state office.

Alumni New York Skin and Cancer Hospital—Graduates of this post-graduate school are requested to send their present professional office address to the secretary of the reorganized Alumni Association.

DR. HERMAN GOODMAN,
15 Central Park West, New York City.

Veterans' Bureau Service Expanded—It is not very widely known that the last congress passed a law authorizing the Veterans' Bureau to extend its hospital and traveling expense service to include veterans of *all wars since 1897* for certain diseases. Under this law "*any person who served in the military or naval forces of the United States during any period after 1897*, except those persons whose discharge from the service was dishonorable, will be furnished treatment at any hospital under the jurisdiction of the United States Veterans' Bureau, when such persons are suffering from neuro-psychiatric or tuberculous ailments and diseases, paralysis agitans, encephalitis lethargica, amoebic dysentery, or the loss of sight of both eyes. The term 'neuro-psychiatric ailments and diseases' will include psychoses, psycho-neuroses, epilepsy, organic diseases of the nervous system, endocrinopathies, Raynaud's disease, sangioneurotic oedema and erythromelalgia. 'Tuberculous ailments and diseases' will include all forms of tuberculosis."

The New Jersey Medical Association, with a membership of 2300, has engaged, at the expense of about \$12,000 a year, a publicity agent or educational instructor, a full-time man. He acts as editor of the state journal, as a chairman of the welfare committee, and will spend his whole time in placing their problems and their matters of medical interest before the medical men of the state and before the people of the community.—A. M. A. Bulletin.

Medicine in the Public Press

An Effective Check to the Socialization of Health—President Coolidge, in his budget message, refers to federal subsidies by saying: "I am convinced that the broadening of this field of activity is detrimental both to the federal and the state governments. Efficiency of the state governments is impaired, as they turn over to the federal government responsibilities that are rightfully theirs. *I am opposed to any extension of these subsidies. My conviction is that they can be curtailed with benefit both to the federal and state governments.*"

In commending the President's stand, the San Francisco Bulletin says editorially that: "If the government is to build the roads, if it is to control education, if it is to be the *universal guardian against disease*, if it is to reforest our hills, and on down the line to *instructing women in the business of maternity*, little will be left to individual initiative and judgment, not to mention *state responsibility*."

Legal Restrictions Embarrass Educator—In a thoughtful editorial (San Francisco Bulletin), Mr. Will C. Wood, State Superintendent of Education, is quoted as saying that he is "getting a bit tired of this eternal saddling of all the problems that civilization can't solve on the school system."

"There are those," continues the editorial, in support of Mr. Wood's contention, "who would make the schools the universal physician, the universal dentist, the universal nurse, the universal provider, the universal entertainer of childhood. There are those who, in enthusiasm for special fads and whims, would make the school, not an agency of instruction and mental training, but a forcing house in support of propaganda in a hundred forms."

"At the next legislature I want to introduce a bill striking out twenty-seven subjects required by law. I would strike out these twenty-seven subjects and in their places insert a few fundamental objects of education, such as lay the basis for all learning that may come later, instilling patriotism and building up character. These would be less easy to tamper with, for the number of virtues is much less than the number of subjects that cranks can suggest. . . . Worst of all is the realization that most of these subjects are but mummified and petrified tributes to the persistence—or beauty—of professional lobbyists in Sacramento."

Mr. Wood ought to have more support than he is likely to get in this praiseworthy objective.

Another Germ Killer—Another professor has discovered another germ killer, according to the newspapers.

This new poison is said to consist of a sort of by-product of the ultra germs that live as parasites upon the ordinary germs that we know about. The ingenious discoverer says his toxin will not kill the tuberculosis germ, but does promptly destroy those of cholera, typhoid, and what not. The modest discoverer apparently considers his work comparable to that of Pasteur.

Let us hope that it is.

An Optimist Writes Fiction—One doctor (variety not specified), according to an editorial (World's Work) predicts that "In fifty years the world will be a world without disease. The most terrible plagues that now afflict mankind will have been conquered by modern chemistry. Even the most baffling will become only the more tragic memories of humankind. A world without disease!" The editor implies wisely that this will require speed because "It would probably be impossible to find today a single human being who is not ill in some way and to some degree."

Every Nut Has a Kernel—"The beliefs of Christian Scientists, so far as they relate to the cause and cure of human disease, are not new revelations in advance of biological science. They are really curious survivals of primitive conceptions, discarded by biologists centuries ago. All primitive people look upon disease as the result

of abnormal 'spiritual' forces. Treatment consists in attempts to expel invading demons, or propitiate angry deities. Christian Scientists have merely reworded these primitive conceptions in terms of orthodox Protestant Christianity."—The Research Worker, Stanford University.

An Important Decision—Attorney-General Webb, according to news dispatches, has ruled that persons licensed as chiropractors and osteopaths are not eligible under the law to receive credentials from the state school department to perform health and development work in the public schools.

Was Everyone Blameless for the Death of Victoria Ortiz?—Nationwide publicity was recently given to the incident in Solano County when the little three-year-old Victoria Ortiz died as a result of burns after being refused admission and service to two hospitals, one a government institution, the other a private hospital. The incident apparently has now been closed by a finding of the district attorney of the county to the effect that no one was to blame for this accident except possibly the parents. It seems that the child was burned one evening and medical attention was not asked until 10:30 o'clock the next morning. Curiously enough, most of the criticism and newspaper editorial comment throughout the country has resolved itself into bitter criticism of the medical profession as the result of this accident. This, in spite of the fact that none of the evidence shows that any doctor at any time was asked to see the child, or did see it, or knew anything about the situation at all until the child was taken into the hospital where it finally received service.

Some good will apparently come out of the incident, in that the county authorities are now negotiating with the private hospital to take care of emergency work in their locality.

Stockton Doctors Complimented—According to newspaper reports, Mrs. Thompson believes Stockton's physicians to be exceptionally competent in treating tuberculosis. Several of the doctors had their patients and diagnoses checked up at the Tuberculosis Clinic held in Stockton recently.

It is becoming quite the fashion for non-medical persons, state bureaus, and other organizations to call in outside doctors to check up on the work of local physicians in certain communities.

Nutrition Expert Holds Clinic—According to news dispatches, "mothers of habitually underweight children are urged to bring them for examination to Miss Woodward, nutrition expert of the State Board of Health, who will hold consultations in a room separate from the examination quarters of the clinic and will give advice on nutrition and dietetics."

Tulare County Health Center Taken Over by Local Officials—Tulare County Health Center, which has been supported largely by voluntary contributions for some time, has been officially taken over by the county as a municipal undertaking. It is anticipated that everyone connected with the center will now be paid except the doctors, who will be expected to continue their services for nothing.

Optometrists Official Examiners of the Eyes of School Children—Optometrist Fred Watson, secretary of the California Optical Company, claims to hold a certificate from the State Board of Education to examine the eyes of children in the public schools. Upon a recent trip to Pittsburg, Calif., he is said to have examined about 200 children. The examinations were free, so far as the children are concerned, being paid for by the association of optometrists.

Drugless Healers Given Credit for California's Health—An editorial in a California newspaper says: "The truth of the matter is that California is the most progressive state in matters of health, and the reason why

it is so healthful is because it has such an abundance of drugless healers, doctors who do not believe in prescribing drugs and serums to cure 'bad habits.'"

Old Age Pensions—An Old Age Pension bill, known as the Murphy bill, will be considered by the Forty-sixth California Legislature. The bill is modeled upon those of Montana, Utah and Pennsylvania, is fostered by the fraternal Order of Eagles, and has the endorsement of organized labor. It is a substitute for poor farms; authorizes a monthly allowance of \$30, to be allocated and disbursed by a state commission to needy persons over 65 years of age.

"Nothing so damns our civilization," says the Daily News editorially, "as the way we treat our aged. Were dependent old age written down as a felony on our penal statutes, we would hardly be more cruel than we are to the aged infirm. For no other crimes than their misfortunes we brand them paupers and herd them into 'poor farms.'"

There, instead of loving care, tender understanding and honor, we dole out a grudging three meals and shelter as forbidding and unbeautiful as a jail.

"Old age, which gave us Moses, Socrates, Epictetus, Erasmus, Tolstoy, Whitman, Anatole France, the seers of every era, must look to China for the veneration it has earned through patient years. California has nothing to offer the aged but a bare living.

"The proposed pension measure would cost no more than the 'poor farms,' and it would permit our old folks to enjoy their declining years among their friends and families."

The principle involved deserves the highest consideration, but like so many other fine idealistic principles it is difficult of practical application.

A wisely drawn and wisely enforced law surely would constitute as definite an improvement over "poor farms" for the aged and permanently disqualified of any age, as does the "home placement" over the "orphanage" for homeless children.

Success in both movements requires careful, wise sustained personal supervision. Many of our elderly dependants are not only physically, but also mentally handicapped, and to give them a cash allowance once a month without thoughtfully applied safeguards would lead to all sorts of undesirable consequences.

The bill deserves serious and careful non-political study by our legislature, and if the principle involved can be made practically workable, it ought to be incorporated into law.

Cancer Cures Below the Average—Only four "new" sure-shot "cancer cures" were given space in the newspapers during the past month.

Are "sure cures" discovered less frequently than formerly, or are editors growing more particular? The latter appears to be the answer, for several of our papers did not mention any of the last four. Other editors gave them brief notice and only a few gave them extensive write-ups.

A Doctor Answers a Patient—In answering a patient's protest against the amount of a fee, a doctor wrote:

"You make the contention that the operation required less than three hours, and that the charge of \$—— is, therefore, entirely out of reason.

"Permit me to point out to you a slight discrepancy in your calculation. As a matter of actual fact, the operation to which you refer required somewhat more than twenty-seven years. That is the period of time which I spent in studying my profession and fitting myself to successfully perform an operation in three hours. Like other medical men, I have no source of income aside from my professional services. And I am sure you will agree that it is only fair to add a certain sum which may be credited to experience, and that elusive thing known as "skill." Pro-rated over a period of twenty-seven years, my charge of —— appears ridiculously small, doesn't it?"

"People Who Live in Glass Houses"—According to "News" dispatches, Mr. Wagner, head of a state bureau, is going to put a lot of private hospitals out of business because they are "veritable fire traps." Why

pick on the private hospitals? If there are any private hospitals worse fire traps than are the majority of government hospitals, we would like to see them. Why should the government have a monopoly on the privilege of housing the sick in "fire traps"?

"Propaganda Against Optometry in Board of Health Bulletin"—Under this headline the California Optometrist says: "How widespread and insidious the propaganda against optometry is becoming is evidenced by the weekly bulletin of the California State Board of Health published on September 6, and which contains an article by Dr. Edward F. Glaser of San Francisco, a member of the State Board of Health, entitled 'Saving Eyesight.' These bulletins are given a widespread circulation, and one copy is mailed to every newspaper in the state."

The part of Dr. Glaser's article which is particularly resented by the Optometrist reads: "Be sure that your eyes or your children's eyes are properly examined by a doctor trained and capable of recognizing and diagnosing the actual conditions and who possesses the knowledge and training necessary in applying the proper remedies, whether medical, surgical, or the wearing of glasses. The public should be taught that eye-strain is a medical problem, and that no one without a definite medical education should be trusted with the differentiation between healthy and diseased eyes."

The editor of the Optometrist seems to think this statement is political propaganda directed against optometrists instead of a simple statement of scientific fact. The editor believes: "That doctors and oculists for the past few years have been viewing with alarm the rapid growth of optometry that has long been recognized by members of the profession, and recently many indications have shown that the medical association is planning to make a hard fight against the inroads optometry has been making on the medical profession."

Poor Monkeys—Four-legged and Two-legged—India is becoming so aroused over the slaughter of their four-legged monkeys to secure "glands" for the "rejuvenation" of two-legged monkeys that the Societies for the Prevention of Cruelty to Animals have entered the field. A Calcutta paper is quoted as saying that: "The European and American craze for rejuvenation is denuding India of its monkeys, the sacred animals being slaughtered so that the senile and debauched may win back a problematical youth."

The editorial warns the government that, unless it forbids this "devilish trade," it will have a terrible responsibility when the consequences of the popular indignation become manifest."

Thoroughly Disgusting—An anonymous writer calls our attention to a disgusting lot of newspaper and magazine clippings upon which he (or she) invites comment:

Case 1—Madam X says she is an "expert" upon "nerves" and that she is a "scalp and skin specialist." If she is doing only what she claims, she is practicing medicine. The Board of Medical Examiners will see if they can get enough evidence to at least make her move.

Case 2—A "specialist for ladies" says, in a San Francisco newspaper, that she has had twenty years' "experience" and has "relieved thousands." Perhaps that is one reason why only 87,000 babies were born in California last year.

Case 3—A Chinese herb company makes marvelous claims of the usual kind. The people of this concern are now under arrest, as they have been several times before. So far, it has been impossible to convict them. To publish the reasons might be libelous.

Case 4—"Doctor —, expert specialist," tells what he can do in many lines. He claims to save the patient money by preparing "medicines in office." The Board of Medical Examiners could perhaps give another reason for his not patronizing a drug store. It ought not to be particularly difficult to get evidence in this instance."

Case 5—Papers in San Diego carry the claims of —, to the effect that several serious maladies are "easily

cured." "Elegant illustrated booklet, 10 cents." The post-office people might be interested in that "booklet."

Case 6—"Cancer victims" are invited to "address physician for circular," says a card in a San Francisco newspaper. We wonder if the newspaper saw that circular before they accepted the responsibility of helping this "physician" promote his scheme.

Case 7—"Dollar Clinic," "all ailments," "medicines included" for a "\$1 fee only." Even at this rate they cannot compete with the "free clinics" nor with the Industrial Accident fees.

Case 8—"Doctor —, spine and nerve specialist," says you can get well quickly by his "soothing treatment."

The newspaper that carries this has just below it (and mixed up with several sorts of healers' conflicting claims made ridiculous by comparison as between themselves) the following:

"The (name of the newspaper) is a member of the Association of Newspaper Classified Advertising Managers, which includes leading newspapers throughout the country, and has for its aim the elimination of *fraudulent and misleading classified advertising*. The —, as well as every other member of the association, endeavors to print only truthful want ads, and will appreciate having its attention called to any advertisement not conforming to the highest standards of honesty."

Good newspapers, like good doctors, try to live up to their ethics.

Why?—"E. E. Simpson will appear before the state convention of chiropractors," says the San Francisco Daily News. "Mr. Simpson is eating tacks, broken bottles, razor-blades, and electric-light bulbs. He once won a wager by eating an automobile windshield."

Does Dancing Prevent Cancer?—According to newspaper stories, a California doctor "who has just returned from a world-wide research expedition" says that it does. As the story goes, the doctor is quite positive that: "In countries where people dance from their youth, cancer is never found!!!"

A Great Newspaper Attacks "Cancer Cure News"—It is heartening to see a great newspaper like the New York Times publishing articles condemning the propaganda that circulates as "news" about "cancer cures." In an intelligently illustrative article recently carried by the "Times," this irresponsible publicity is classed as a menace.

"This menace lies in the deluge of so-called cancer 'cures' which is flooding the country. Some of these cures are advertised with transparently evident commercial design and some are put forward with an attempt to simulate conservative procedure, almost deceiving the medical profession itself. Between the two are many varieties; some are promoted by persons who are so ignorant that their written communications are grotesque—and written communications are frequent in connection with proprietary cancer cures, for the promoters draw their patients from a large territory. . . . No one can fail to appreciate the emotional reaction of a woman who is suffering from what she believes to be a disease with only one end, when she reads in the newspapers that such and such a person has discovered a cure for cancer. She immediately seizes upon the hope that is offered to her, and believes the claims that are made; and the wish, which under such circumstances is so naturally the father of the thought, endows the cure with every virtue its promoter may have forgotten to ascribe to it. And the friends and relatives of patients look on and share in the delusion."

The business of cancer cure fakirs would be promptly reduced 75 per cent if all newspapers would refuse to publish anything about cancer not endorsed by competent medical opinion.

"A university education will be broadcast by radio in Berlin. Similar cases will become common in America later. The majority, of course, want entertainment when they listen in. But there are millions who would welcome the chance to get a college education at night, being

unable to afford personal attendance. Radio and the movies will be the greatest future educators."

United States Government Makes Huge Profits Out of Narcotic Problem—According to official reports, the federal government collected through narcotic taxes for last year \$1,057,066.33, and it cost \$709,790.66 to administer the law. Therefore, our government got a profit out of its narcotic business of more than \$300,000. Many doctors would like to know if it is because of the profits in the business that the government still refuses to modify the war tax on doctors.

Shall Doctors "Unionize"?—It may seem strange to some people that highly educated physicians and surgeons should organize a labor union and fix a scale of wages, but there is nothing either odd or wrong about it. Those Washington doctors who formed such a union merely made use of their intelligence and took a step which ought to be beneficial both to them and to the public.—San Francisco Daily News.

Anaphylactic Shock Following Use of an Organic Coagulant—Bernard E. Sayre, Chicago (Journal A. M. A.), relates a case of a severely toxic goiter in a man, aged 30, in which, after enucleation of the gland, a continual oozing on the left side of the trachea could not be stopped. As the bleeding was very close to the recurrent laryngeal nerve and ligation not practical because of danger of injury to the nerve, an organic blood coagulant (coagulose) was applied to the bleeding surface, the area packed with gauze, and the incision sutured in the usual manner. The blood pressure before operation was 160 systolic and 80 diastolic. During operation it rose to 180 systolic and 90 diastolic, and at the close of the operation the blood pressure had dropped to 165 systolic and 85 diastolic, with a pulse of 120. The patient was breathing well and appeared in good condition. About fifteen minutes after the application of the blood coagulant, the patient suddenly became cyanotic, breathing with great difficulty and inspiring in short gasps. Foam appeared at the mouth. Within a minute or so, breathing ceased. The heart became rapid and the pulse somewhat weak, but continued to beat regularly. Artificial respiration was resorted to; stimulants were given hypodermically; oxygen was administered, and breathing was finally resumed. Cyanosis lasted for ten minutes. The patient remained unconscious for two hours afterward, although ether was not given at any time during the operation, and the gas anesthetic had been stopped fifteen minutes previous to the onset of dyspnea.

The Swing of the Pendulum—It is evident, believes E. H. Oschner, that the pendulum is already beginning to swing the other way and that the older clinical methods are gradually coming back. . . . Some of the refinements in diagnosis and treatment which are now in vogue are unquestionably very interesting to the research worker and in part may ultimately be of some real benefit to medicine. But the questions which the man who actually teaches under-graduate students should ask himself are, "Have they proven their dependability and are they of sufficient fundamental importance for the student to spend his time on in the present stage of his educational career?" While a certain small number of cases require some refined diagnostic methods, in the great majority of cases such ultra-refinement is not necessary and often not desirable because it only too often tends to confuse rather than to clarify. The x-ray in gall-stones, for instance, misleads more often than it aids. Let us remember that, after all, the five well-trained senses are usually indispensable in reaching a correct diagnosis, and let the teacher ever emphasize this point and do everything in his power to teach the student the proper use of these senses; not to the exclusion of the other diagnostic methods, but with the understanding that the percentage of errors in conclusions, based upon a careful examination of a patient by the unaided senses, is much smaller than the percentage of error in conclusions based exclusively upon almost any one of the more modern ultra-scientific diagnostic methods.

California Medical Association

GRANVILLE MacGOWAN, M. D., Los Angeles..President
EDWARD N. EWER, M. D., Oakland.....President-elect
EMMA W. POPE, M. D., San Francisco.....
.....Secretary and Associate Editor for California

A. M. A. FELLOWSHIP

Fellowship and membership in the American Medical Association are often incorrectly used as synonymous. They are not identical, and members of the California Medical Association are frequently surprised to learn they have not automatically been made Fellows of the A. M. A. by reason of their state membership.

When the county secretary reports a new member to the state association, his name is forwarded to the A. M. A., and he is then listed as a member and not a Fellow of the A. M. A. Should he desire Fellowship, he must make special application for it upon a blank provided, which can be obtained from the state office, 1016 Balboa building, San Francisco. A check of \$5 must accompany the application, of which \$4 is credited to a subscription to the A. M. A. Journal and the A. M. A. Bulletin. If the A. M. A. Journal is not desired, one of the six publications listed on the back of the application blank can be substituted.

Loss of membership in the state association automatically debars from both membership and Fellowship in the A. M. A.

Only Fellows can actively participate in the program of a national meeting. The right to hold office or to vote is also contingent on Fellowship status. Delegates from the C. M. A. to the A. M. A. must have been Fellows in good standing for the preceding two years.

REAPPORTIONMENT OF DELEGATES
TO A. M. A.

(Important letter from Doctor Olin West)

September 27, 1924.

The triennial reapportionment of delegates from constituent state and territorial medical associations was effected at the Chicago annual session of the American Medical Association in June of this year. The reapportionment of delegates was on the basis of one delegate for each 950 members or fraction thereof for all constituent associations having a recorded membership of 950 or more. Under the provisions of the by-laws, each constituent association with smaller membership is entitled to one delegate.

The records of this office show that, on April 1, 1924, the California Medical Association had reported 3929 members for enrollment. The California Medical Association will be entitled to five delegates in the House of Delegates of the American Medical Association in 1925.

There are now pending proposed amendments to the constitution and by-laws providing for an increase in the voting membership of the House of Delegates. It is quite probable, therefore, that a new apportionment of delegates will be effected in 1925.

ANNUAL SESSION C. M. A., YOSEMITE, MAY 18, 19, 20, 21, 1925.

How do we get there and where do we stay after we arrive?

Those are the two big questions in connection with any convention, not excepting those held in such a well-known place as Yosemite. Both will be answered here as briefly and as comprehensively as possible for the benefit of those who will attend the annual meeting of the medical society of the state of California, May 18-21, 1925.

Yosemite National Park, most popular of all the nation's parks, lies almost due east of San Francisco, in the heart of the Sierra-Nevada Mountains, and is reached by railroad and by several good automobile roads. Main lines of both Southern Pacific and Santa Fe, in the San Joaquin Valley, between San Francisco and Los Angeles, pass through Merced, from where the Yosemite Valley railroad leads up the beautiful canyon of the Merced River to El Portal at the park boundary. A government highway that is like a boulevard extends from El Portal fifteen miles farther up the canyon to Yosemite Valley, the heart of the park. The drive from El Portal to Yosemite, as the village is known, is a matter of an hour, in the comfortable motor-cars of the Yosemite Transportation System, one of the most spectacular hours in a lifetime, for the broad road leads through a panorama of cliffs, and forests, and waterfalls that has no superior anywhere in the world.

On this ride, the visitor passes through the famous "Gates of Yosemite," where El Capitan towers 3604 feet on the left, with Three Graces making a perfect background for Bridal Veil Falls on the right, and Clouds Rest and Half Dome looming up in the middle distance.

The rail journey from Merced to El Portal is only seventy-eight miles, a trip of about four hours through famous placer mining country still scarred by the activities of '49. Detailed schedules and fares from all principal points in the state will be furnished later.

The Wawona road, ninety miles from Merced to Yosemite, paved or macadamized for thirty-eight miles of that distance, probably will be the best road for the use of those who will go to the convention in their own machines, as the Big Oak Flat road sometimes does not open until later because of snow on the higher altitudes. However, road conditions depend on the season, and the weekly bulletin of the superintendent of Yosemite Park, distributed to all agencies of the California State Automobile Association and the Automobile Club of Southern California, might well be consulted before starting the trip to ascertain just what roads are open.

Arriving in Yosemite Valley, Sentinel Hotel and Yosemite Lodge will receive the visitors. The Sentinel is situated in the village, while the Lodge is across the river, less than one-half mile distant, in a grove of pines at the foot of Yosemite Falls. Both offer accommodations and service of the highest type, the Sentinel having its living quarters in rooms, with and without private bath, in a main and annexed buildings, and the Lodge having the cabin plan of accommodations, individual houses, with and without private bath, grouped around an attractive community center.

Unobtrusive service and supremely good food have made the Sentinel favorably known to even the most jaded of globe-trotters. It is one of the few hotels in the world electrically equipped throughout, all heating, lighting and cooking being done by hydro-electric power. It also is one of those rare hostleries which are operated on an "unlimited" policy in the kitchen, the chefs being unrestricted in their use of good things, so that the Sentinel justly claims the highest per capita consumption of cream, butter and eggs of any hotel on the Pacific Coast.

Rates at the Sentinel (American plan) are \$6 a day per person in rooms without private bath, and \$8.50 a day per person in rooms with private bath. All rooms are outside rooms and nearly all rooms are equipped with twin beds.

The cabin type of resort, frequently encountered in the West, has reached its highest development in the American plan accommodations of Yosemite Lodge.

Redwood cabins with private baths, many of the cabins

also having screened sleeping-porch, may be had for \$8.50 per person per day, American plan. A generous porch gives entrance to a bedroom equipped with twin beds and other furniture of attractive design, and heated by 5000 Watt electric heaters. A dressing-room or large closet provides ample space for hanging clothes. The bathrooms are equipped in spotless porcelain.

Redwood cabins without private bath make up the second group and are furnished similarly to those having baths, except that bowls and pitchers take the place of running water, and small stoves burning fragrant pine or cedar wood are used for heating. The American plan rate is \$6 per person per day.

Canvas cabins form the third group—and do not confuse the Lodge's canvas cabins with tents. Canvas cabins here are all that the name implies, houses with canvas for walls. They are floored, of course, and electrically lighted. Entrance is by a screen door, and there are six screened windows with curtains and awnings. Furnishings are similar to those in redwood cabins without bath, and the charge is \$1.50 and \$2 per day per person on the European plan, or \$6 per day per person on the American plan.

Maid service in all classes of cabins assures plenty of clean towels and, in the cabins without baths, fresh water. Hot water for the morning toilet may be had without extra charge by those living in cabins without baths, if they will leave cabin number and hour desired with the Lodge office. Detached baths and sanitary flush toilets are located conveniently.

Reading room, writing room, dining room, broad verandas, soda fountain and curio and news shop are included in the main building of Yosemite Lodge, with outdoor dancing pavilion and theater for evening entertainments just in front. Individual service at table is a feature of the Lodge's American plan dining room, where excellent food is appetizingly served.

Both the Sentinel and the Lodge are near the village, the government pavilion, and other places where clinics and sections will meet, but for the benefit of those who do not wish to walk, a local service automobile will be operated over the floor of the valley, following a regular route just like a street-car, the fare being reduced to 10 cents, for the benefit of the medical society.

Inquiries regarding transportation to Yosemite, trips inside the park to Hetch Hetchy, the Big Trees and Glacier Point, and hotel accommodations, should be addressed to H. H. Hunkins, traffic manager, Yosemite National Park Co., 511 South Spring street, Los Angeles, Calif., who is acting as chairman of the transportation and hotel committee for the convention.

COMMERCIAL EXHIBIT AT YOSEMITE

The attention of the advertisers in CALIFORNIA AND WESTERN MEDICINE is called to the ruling of the executive committee of the California Medical Association, that, owing to the small demand for a commercial exhibit in Yosemite, no special provision for space has been made, but that advertisers in CALIFORNIA AND WESTERN MEDICINE, and *advertisers only*, are privileged to make arrangement for exhibit space direct with the Yosemite Lodge Company, should they so desire. Credentials will be furnished, on request, by the secretary of the California Medical Association.

ALAMEDA COUNTY

Alameda County Medical Association—(reported by Pauline S. Nusbaumer, secretary)—The annual meeting of the Alameda County Medical Association was held December 15, 1924.

F. B. Taylor reported a case of carcinoma of the stomach, the interesting feature being the fact that the x-ray failed to demonstrate the lesion because it was located posteriorly. The clinical diagnosis was confirmed by the necropsy.

The association is indebted to A. C. Siefert for the following symposium on duodenal diverticula: X-ray diagnosis, with lantern slides, A. C. Siefert; surgical aspect,

A. C. Dukes; medical aspect, S. V. Irwin; differential diagnosis, F. B. Taylor.

S. C. Irwin being unavoidably absent, F. B. Taylor incorporated some of the medical aspect in his talk.

A. C. Siefert, in his paper, reported six cases. He stated that diverticula are more common than is ordinarily supposed. The doctor quickly considered pathologically two general types. He claims that the diagnosis is not possible on clinical data alone, but the x-ray examination is necessary, and the fact that diverticula may become inflamed, and enlarged to a considerable size, makes them of surgical importance.

C. A. Dukes said surgery of diverticula of the duodenum differs but slightly from other surgery of the duodenum. He called attention to the difficulties encountered in trying to operate upon small diverticula, because of the difficulty of locating them at the time of operation. Although they may seem perfectly plain in the picture, in operating they are sometimes most difficult to locate, especially posteriorly.

In a recent case, x-ray showed a definite diverticulum about two inches in diameter in the second portion of the duodenum, posteriorly. At operation the diverticulum was found distended with gas to the size 8 x 5 cm., pedunculated, wall very thin, ruptured during dissection. The diverticulum was adherent and was situated under the lower border at the head of the pancreas. Because of adhesions, the diverticulum was exposed with difficulty; it was freed to base by blunt dissection. There was considerable gas, and some contents of a reddish brown-like fluid escaped during the proceedings. Purse-string of plain catgut, two layers; rubber tube drain at site of operation; usual abdominal enclosure. This man made an uneventful recovery.

The lesson we have learned on duodenal diverticula is to hesitate in operating upon all cases. He thinks that judgment should be used in the type of cases to be operated upon.

In his paper, F. B. Taylor said: "The duodenum is the most sensitive viscus in the upper abdomen. It has a richer blood supply, a faster muscular rhythm, and a more rapid chemical activity than any other part of the digestive tract. It is the segment of greatest physiologic activity in that department which is responsible for human nutrition. Furthermore, the duodenum is as sensitive as it is active, and shares the discomforts of its nearest anatomical neighbors when they are in trouble. The diseases of many of the upper abdominal viscera are characterized by one or more symptoms which are parts of a "duodenal syndrome." It is not strange, therefore, that cholecystitis, bile-tract disease, pancreatitis and partial block of the upper jejunum give a similar train of symptoms all depending upon an interruption of the normal gradient of forces present in a healthy digestive tract. The duodenum informs its owner that there is upper abdominal trouble, and collateral signs and symptoms help make the diagnosis. But when the duodenum itself is diseased, so closely is it surrounded by its anatomic and physiologic neighbors, that it may present very little differential symptomatology. That is especially true when the mucus membrane is unbroken, as in diverticulitis. The diagnosis of this condition, therefore, is not a clinical one; it is made by the roentgenologist or surgeon.

Following the scientific program, the chairman of all standing committees and the chairman of each of the commissions, the secretary-treasurer, and president read their reports, all of which were ordered filed. The tellers not being ready to report, the meeting adjourned to the lower hall and enjoyed a social time while partaking of refreshments.

The election, according to the report of the tellers, resulted as follows: President, H. B. Mehrmann; vice-president, J. K. Hamilton; secretary-treasurer, Pauline S. Nusbaumer. Councilors: L. P. Adams, G. G. Reinle, Gertrude Moore, C. A. DePuy, Guy Liliencrantz, and Sumner Everingham. Delegates: C. L. McVey, Pauline S. Nusbaumer, and A. M. Meads. Alternates: F. H. Bowles, Henning Koford, R. T. Legge, C. A. DePuy, A. H. Rowe, and W. L. Channell.

CONTRA COSTA COUNTY

Contra Costa County Medical Society (reported by L. St. John Hely, secretary) — The twenty-fifth annual banquet and election of officers of the Contra Costa County Medical Society was held Saturday, November 29, 1924, at 8 p. m. at the Berkeley Country Club. The following officers for the year 1925 were elected: President, Marguerite Deininger-Keser; vice-president, G. M. Bumgarner; secretary-treasurer, L. St. John Hely. Delegates: U. S. Abbott and Deininger-Keser.

C. L. Abbott was toastmaster. F. B. La Moine spoke on "Drugs." Rev. T. A. Boyer entertainingly responded to "the ladies"; and Mrs. C. R. Blake received a hearty response for her talk on "the gentlemen." Hiram Jacobs, Assistant District Attorney, covered the subject of "Medical-Legal" thoroughly.

The society was indebted to W. A. Clark of Oakland for the presentation of his famous views photographed in actual colors. This feature of the entertainment was worth the "price of admission." The society wishes to thank him for the favor.

The following were present: Doctors and Mesdames U. S. Abbott, Beard, Bumgarner, Clark, Cole (dentist), Carpenter, Cunningham, Hely, Horne, Lipp (dentist), O'Brien (dentist). C. L. Abbott, Blake, Belgum, Breneman, Clara Spalding, J. B. Spalding, Hall Vestal and two daughters, Eleanor Axelsen, Agnes Driscoll, R. N.; Elizabeth Redmond, R. N.; Mrs. H. K. Youd, R. N.; and Elizabeth McKenzie, R. N.

FRESNO COUNTY

Fresno County Medical Society (reported by T. Floyd Bell, secretary) — A meeting of the board of governors was held in Dr. Morgan's office December 16, 1924, at 1 p. m. The following were present: Drs. Cross, Miller, Tillman, Trowbridge, Morgan, T. Bell.

Bills were audited and ordered paid.

Dr. Trowbridge moved, Dr. Miller seconded, that the following resolutions be adopted, that publicity be given in the papers, and that the Supervisors be interviewed personally in regard to this matter. Carried.

"WHEREAS, It has come to the attention of the Fresno County Medical Society that a movement is on foot to rescind Ordinance No. 218 of Fresno County; and

"WHEREAS, Said Ordinance No. 218 contains provisions for the compulsory vaccination of dogs against rabies, and

"WHEREAS, The vaccination of dogs against rabies is the best known method for combating and preventing the spread of rabies, and

"WHEREAS, The rescinding of this Ordinance No. 218 would be a step backward in the progress of preventive medicine by doing away with compulsory vaccination of dogs against rabies, and

"WHEREAS, The rescinding of compulsory vaccination against rabies would undoubtedly lead to serious outbreaks of rabies in the future, and

"WHEREAS, Outbreaks of rabies are a serious menace to the health of the citizens of Fresno County, now, therefore, be it

"RESOLVED, That we, the Fresno County Medical Society, go on record as opposed to any legislation that will rescind the provisions in Ordinance No. 218, relative to the compulsory vaccination of dogs against rabies, and be it further

"RESOLVED, That a copy of these resolutions be sent to each member of the Board of Supervisors for Fresno County."

Dr. Trowbridge moved, Dr. Miller seconded, that the dues for 1925 be \$15. Carried.

Dr. Miller moved, Dr. Tillman seconded, that the secretary investigate the matter of associate members of the society so that such men who are qualified may be asked to join. Carried.

Dr. Miller moved, Dr. Bell seconded, that the Chair appoint a committee, the secretary being one, to make necessary changes in the by-laws and constitution to con-

form with the state society. Carried. Drs. Cross, Miller, and Bell were appointed.

A special meeting of the Fresno County Medical Society was held December 20, 1924, with luncheon at the Hotel Fresno.

Twenty-two members and six visitors were present. Members: Aller, Anderson, Bell, Butin, Goldberg, James, Kjaerbye, G. L. Long, Luckie, Madden, Milholland, McPheeters, Pettis, Pomeroy, Sheldon, Tillman, Trowbridge, and Tupper.

Visitors: Betts, Butin, Seligman, Preston, Woolf, and Mr. J. D. K. Perry of the "Republican" staff.

Dr. C. Mathewson gave a short talk about his visit recently to Los Angeles in regard to the plague situation, and asked this society to give its support to the Board of Health in asking for \$5000 for rat eradication in Fresno.

Dr. Luckie moved, Dr. Kjaerbye seconded, that this body, through its board of governors, endorse the request of the Board of Health for \$5000 for ridding the city of rats.

The following letter was sent Mayor Hart, in regard to the last-named affair:

"Hon. T. G. Hart, Commissioner of Public Health and Safety, City Hall, Fresno, Calif.

Dear Mayor Hart—The board of governors of the Fresno County Medical Society, meeting December 20, 1924, do hereby endorse most heartily the request of the Board of Health of Fresno for \$5000 for a campaign against rats, as this is the most efficient means of preventing plague in human beings, and so avoid, if possible, an epidemic of plague such as occurred recently in another city in California.

Respectfully yours, John D. Morgan, M. D.; D. H. Trowbridge, M. D.; W. W. Cross, M. D.; W. P. Miller, M. D.; E. J. Couey, M. D.; Frank Tillman, M. D. By T. Floyd Bell, secretary."

Dr. M. S. Woolf of San Francisco gave an instructive and interesting paper on "Ulcerative Colitis." He said that this is a rare disease, of non-specific etiology as far as known, but often associated with streptococci. It was just described as an entity in 1883. It is almost always fatal if no surgery is used, while almost 80 per cent are cured by surgery unless very far advanced. The ulceration usually begins in the rectum, and a sigmoidoscopic examination is invaluable. It usually ascends and involves the whole colon and stops at the caecum. Patients die from anyloid disease and perforation. The symptoms are many: watery, bloody, mucous stools, with some cramps. These patients suffer great thirst. Remissions are typical and may last for years. The diarrhoea is very severe. Differential diagnosis must be made from amebic infection and bacterial infections, such as tuberculosis or typhoid. The surgical treatment consists in an early enterostomy. The paper was well discussed by Pettis.

The meeting of the board of governors of the Fresno County Medical Society was held in Dr. Morgan's office January 5, 1925. Those present were Cross, Couey, Miller, Morgan, Tillman, Trowbridge, and Bell.

Dr. Trowbridge moved, Dr. Miller seconded, that a committee of three be appointed to confer with the City Commissioners in regard to a rat campaign and to insist that an appropriation of \$5000 be made for this work. Carried. Drs. Cross, Trowbridge, and Pettis appointed.

Dr. Miller moved, Dr. Trowbridge seconded, recommending that the secretary's annual report be accepted. Carried.

Dr. Miller moved, Dr. Tillman seconded, recommending that Dr. O. W. Steinwand be placed on the honorary list.

The regular meeting of the Fresno County Medical Society was held January 6, 1925, at the nurses' home of the General Hospital. There were twenty-six members and ten visitors present. Members: Aller, Anderson, Bell, Burks, Couey, Cross, Diederich, James, Jorgensen, Konigsmacher, Kjaerbye, Manson, Mathewson, Miller, Milholland, Nedry, Peterson, Pettis, Sciaroni, Sheldon, Stein, Tillman, Tobin, J. R. Walker, Wiese, and Willson. Visitors: Drs. Pierce, Charles Brown, Phillip, Dick, and internes at the General Hospital.

The minutes of the previous meetings were read and approved.

The application for membership of N. J. Dau of Fresno

was read and ordered placed in the proper channels for action.

O. P. Pisor of Monmouth was unanimously elected a member, having been passed on favorably by the board of censors and the state secretary.

The following officers for 1925 were elected unanimously, no offices for 1925 being contested: President, A. E. Anderson; first vice-president, W. G. Milholland; second vice-president, Charles A. James; secretary, T. Floyd Bell; assistant secretary, J. A. Montgomery. Delegates: T. F. Madden, H. J. Craycroft. Alternates: B. Lamkin, R. B. Tupper. Board of governors, W. P. Miller.

The secretary's annual report was read and adopted.

Madden moved, Tillman seconded, that O. W. Steinwand be placed on the honorary list.

George Warren Pierce of San Francisco gave an illustrated talk on Plastic Surgery. He said that plastic surgery was much advanced, due to disfiguring and incapacitating wounds of the Great War. Plastic surgery is a crude way and dates back to ancient times as far as 3000 years ago. It was done by the tile craft then. Probably two things have advanced plastic surgery more than anything else in the last few years. They are the tubular and Esser skin grafts. Dr. Pierce showed lantern slides, demonstrating the use of such grafts.

A buffet luncheon was served after the meeting.

A meeting of the board of governors of the Fresno County Medical Society was held January 8, 1925, in Dr. Anderson's office.

Those present were Cross, Couey, Anderson, and Bell.

Miller moved, Cross seconded, that the secretary be authorized to complete arrangements for a speaker to come here in regard to the plague situation and appear before the luncheon clubs; also to prepare leaflets for distributors. Carried.

❧

KERN COUNTY

Kern County Medical Society (reported by W. H. Moore, secretary)—The annual banquet of the Kern County Medical Society was held at the Elks Club, Bakersfield, December 18, 1924, and the following officers were elected for the succeeding year: William H. Moore, president; A. W. Moodi, vice-president; K. S. McKee, secretary-treasurer; P. J. Cuneo, censor; F. A. Hamlin, delegate; and F. J. Gundry, alternate. The society fixed the dues for the coming year at \$17.

❧

MARIN COUNTY

Marin County Medical Society (reported by J. H. Kuser, secretary)—The annual meeting of the Marin County Medical Society was held on December 18, 1924, in Doctor Jones' office in San Rafael. Present: Dufficy, Jones, Clark, Hund, De Lancey, Kuser. Annual dues were fixed at \$11.

Officers elected for 1925 were: President, H. O. Hund; vice-president, W. F. Jones; secretary, J. H. Kuser. Trustees: H. O. Howitt, J. H. Kuser, H. O. Hund. Delegate, R. G. Dufficy. Alternate, C. A. De Lancey.

❧

MONTEREY COUNTY

Monterey County Medical Society (reported by Wiley Reeves, secretary)—At the annual meeting held on December 5, 1924, the following officers were elected for the year 1925: William Rollin Reeves, president, W. H. Bingaman, vice-president; E. Wiley Reeves, secretary; T. C. Edwards, treasurer.

The delegates for the 1925 convention are: Delegate, E. Wiley Reeves. Alternate, W. N. Bingaman.

Dues of the Monterey County Medical Society were fixed at \$12 per member, which includes both state and county society dues for 1925.

❧

SACRAMENTO COUNTY

Sacramento Society for Medical Improvement (reported by G. J. Hall, secretary)—The regular annual meeting of the Sacramento Society for Medical Improvement was held December 16, 1924, President Dr. Drysdale presiding. Members present, 33.

The minutes of the last annual meeting not at hand, secretary apologized for his delinquency.

Dr. Drysdale, in making the board of director's report, touched upon the important points of the meetings of the past year. Briefly outlined, his paper reported that: 1. Business is not interesting to members. 2. Scientific papers read by local men are most productive. 3. Discussion previously programmed is most active. 4. Interesting cases were reported. 5. There was only one outside speaker during the year. 6. Meeting place discussed. 7. Annual banquet. 8. Eulogy expressed on death of Dr. J. W. James.

S. E. Simmons and George Joyce Hall were appointed to draft a resolution on the death of Dr. J. W. James, to be spread on the minutes and a copy to be sent to Mrs. James.

Secretary's report was read and placed on file.

Drysdale, Cress and Scatena, Dillon, Harris and Dunlap were elected as directors.

Drysdale and Dunlap were elected as delegates; Doctors Hale and Jones as alternates. Dr. Thomas was elected secretary.

It was properly moved and seconded that the dues for the coming year be \$15. Carried.

Letter of Dr. J. M. Hamblin, in regard to Industrial Accident fees (addressed to Dr. C. B. Jones), was read to the society and discussed by Dr. Parkinson.

SAN BERNARDINO COUNTY

San Bernardino County Medical Society (reported by E. J. Eytinge, secretary)—The society met at the San Bernardino County Hospital, January 6, 1925. There were 31 members present, 55 absent, 10 guests.

B. R. Davidson of San Bernardino was admitted to membership.

The program was as follows: "Report of a Case of Abdominal Pregnancy, With Brief Discussion"—E. L. Tisinger. Discussion opened by H. W. Mills. "Ectopic Pregnancy"—C. G. Hilliard. Discussion opened by Philip Savage. "The Posterior Occiput Position"—Norman H. Williams, Los Angeles. Discussion opened by H. G. Hill.

The society will endeavor to keep on hand such sera as cannot be procured at short notice from commercial sources. These sera will be kept at the County Hospital for use by any member of this society. Through the courtesy of the Department of Health of New York, we have five bottles of Type A and ten bottles of Type B botulinus serum. Through the Mayo Clinic, we have a small supply of anti-poliomyelitis serum. Attention is directed to the necessity of using the above at the earliest moment. In March we have been promised a tube of rattlesnake anti-venene.

The president has appointed the following as a radio committee: C. L. Curtiss, C. F. Whitmer, and F. F. Abbott.

The secretary acknowledges a communication from the Sophomore Medical Class of Loma Linda, thanking the medical society for inviting them to attend Dr. Pinness' clinic.

Dues for the ensuing year are now payable and are fixed at \$15, \$10 of which goes to the state society.

SAN DIEGO COUNTY

San Diego County Medical Society (reported by George B. Worthington, secretary)—The annual meeting of the San Diego County Medical Society was held at the San Diego Hotel at dinner December 9, 1924. The meeting was well attended, and was presided over by Doctor Thornton. An invitation to hold the January meeting at Camp Kearny was extended by Major Simpson, chief of staff, and was accepted.

The following officers were elected for the ensuing year: President, G. B. Worthington; vice-president, T. F. Wier; secretary, C. O. Tanner; treasurer, W. O. Weiskotten. Councilors: Marjory Potter, H. S. Anderton, E. F. Chamberlin. Delegate, Martha Welpton. Alternate, Lillian Mahan. Milk Commission: H. A. Barclay, five years; L. R. Knorr, four years; W. W. Russell, three years; T. A. Parker, two years; A. B. Wessells, one year. Library directors: Frank Carter, Eager, Geistweit, Howard, Jennison, Jorgenson, Kyes, Murdock, Pollock, Redelings, Rees, Stallard. Secretary-treasurer, W. O. Weiskotten.

The question of the formation of a publicity bureau

was brought up by Thornton, and, after full discussion, an assessment of \$10 was levied "to cover the expenses incident to the publication in the San Diego Union of regular weekly articles, in the nature of educational propaganda, which will be able to give the people as a whole a better insight into what medicine is doing and what it is trying to accomplish for the good of the community." A full discussion of this plan appears in the bulletin of the San Diego County Medical Society of December 19.

Doctor P. B. Magnusen of Chicago gave a most interesting, instructive and practical talk, well illustrated with lantern slides on non-surgical types of backache. His paper was discussed by Doctors Fox, Harding, Churchill, and Doig.

At the conclusion of the program, Thornton thanked the officers and members of the medical society for their co-operation and help during the year 1924, and commented particularly on the great efficiency of the program committee.

Mercy Hospital—The fine new million-dollar hospital, financed, constructed, and conducted by the Sisters of Mercy, is now open and serving the people of San Diego. An illustrated description of the hospital, prepared by Doctor Robert Pollock, appears in *Better Health* magazine.

SAN FRANCISCO COUNTY

San Francisco County Medical Society (reported by J. H. Woolsey, secretary)—The January bulletin of the San Francisco County Medical Society contains the following interesting news:

Radio Medical Talks—The San Francisco County Medical Society has consummated an arrangement with the broadcasting station of the Radioart Studio, Station KFRC, to radiocast health talks and medical information.

Any member of the society may apply to the radio committee for placement on the radiocast program. The names of speakers, their introduction, the subject matter of talks, etc., are all subject to review by the radio committee two weeks before talk is to be given.

KFRC has, to date, broadcasted the following medical talks by members of this society:

September 26, 1924—Outline of health service. Joseph Catton.

October 1, 1924—How other sciences have helped medicine preserve health. E. S. Kilgore.

October 8, 1924—The doctor's biggest job (warding off old age). A. C. Reed.

October 15, 1924—Care of common skin affections. H. E. Alderson.

October 22, 1924—How to live longer. S. H. Hurwitz.

October 29, 1924—Making healthy minds in childhood. W. P. Lucas.

November 5, 1924—Getting thin. Rene Bine.

November 12, 1924—How to avoid cancer. A. R. Kilgore.

November 19, 1924—How prenatal and postnatal care make for future health. W. C. Hassler.

November 26, 1924—How child guidance clinics prevent future failures. R. L. Richards.

December 3, 1924—Why heart disease has become one of the main causes of death. P. K. Brown.

December 10, 1924—How to avoid contagious diseases. A. A. O'Neill.

December 17, 1924—Reconstruction of body parts through plastic surgery. G. W. Pierce.

These talks should take about ten minutes. They are given on each Wednesday evening at about 9 o'clock from the broadcasting station of the Radioart Studio, located at the Hotel Whitcomb.

Advertising Cards of Physicians—The board of directors desires to communicate to the members that it is against the policy of the society to place professional cards in so-called lay directories and other publications serving similar purposes.

The officers elected for the year 1925 are: President, LeRoy H. Briggs; first vice-president, J. F. Cowan; second vice-president, Adelaide Brown; secretary-treasurer, J. H. Woolsey; librarian, Leo Eloesser. Board of directors: Rene Bine, W. W. Boardman, W. R. P. Clark, H. W.

Gibbons, Sol Hyman, William Ophuls, and R. K. Smith. Delegates: W. R. P. Clark and E. S. Kilgore. Executive committee: M. R. Gibbons, chairman; W. J. Kerr, and H. G. Mehrrens. Committee on admissions: Lloyd Bryan, chairman, K. L. Schaupp, and F. H. Zumwalt.

At the meeting of the Eye, Ear, Nose, and Throat Section of the San Francisco County Medical Society on November 25, 1924, the following officers were elected for the ensuing year: Chairman, Otto Barkan; secretary, Warren D. Horner.

The program was as follows:

1. Demonstration of case of intra-ocular copper foreign body—Kaspar Pischel.

2. Paper: "Further Observations on the Use of Adrenalin in Glaucoma"—Kaspar Pischel.

Synopsis—Doctor Pischel, speaking on further observations on the use of epinephrine in glaucoma, pointed out that epinephrine is the official name of the drug; adrenalin is a proprietary name. The solution on the market contains a small amount of chloretone.

Pischel, in relating his own experience in eighteen cases, stated that, in simple and chronic glaucoma, the pupils were always dilated and the tension lowered in complicated cases. Where operation had been performed the results were not uniform.

The dilatation of the pupils is very desirable for ophthalmoscopic examination and in cases of iritis. In the latter cases the injection causes considerable pain. Dr. Pischel then showed a case of glaucoma apparently caused by a piece of copper being lodged in the ciliary body for the last twelve years. It had produced the so-called sunflower opacity of the lens. The greenish opacity of the lens is caused by deposition of copper salts between the capsule and the epithelium. Fundus showed total excavation of disc. Tension was reduced by adrenalin injection of 0.3 from 43 to 30. The pupil, 3 mm., was dilated to 8 mm. The sight was 2/30; field very much contracted. (An attempt to remove the foreign body failed. Cyclodialysis done immediately after this attempt did not reduce the tension; therefore, iridectomy was made several days later.)

Discussion by Dr. Hans Lisser—It is interesting to hear this report, which provides another example of the extraordinary pharmacodynamic powers of this remarkable drug adrenalin. It occurs to me that its action in reducing intra-ocular tension, as in glaucoma, bears some similarity to its potency in angioneurotic edema, in giant urticaria, or in the urticaria of serum sickness, where swellings are made to vanish with amazing rapidity.

This beneficent action of adrenalin does not necessarily permit the deduction that we are dealing with an adrenal insufficiency, in the endocrine sense of this term. From this therapeutic effect alone we are not justified in concluding that glaucoma, or, for that matter, asthma or angioneurotic edema, are ductless gland diseases. We could as well diagnose hypopituitarism during labor, since injection of pituitrin hastens expulsion of the fetus.

Nevertheless, an incretory participation either in the origin or sudden appearance of glaucoma is not unlikely. Indeed, such a conception has been supported by several considerations and advanced by several authors. Imre has even suggested determinations of intra-ocular tension as a diagnostic aid in endocrine diseases (this requires further study). Hertel found that patients with hyperfunction of the thyroid have low intra-ocular tension, and patients with glaucoma have signs of hypofunction of the thyroid. In a case of pregnancy, complicated by osteomalacia, Imre found an extraordinarily low tension of 5 mm. Hg., lower than that of a cadaver. Fridenberg considers glaucoma from the endocrinological point of view as an exudative or hypersecretory disturbance due to sudden failure of vagus tone under sympathetic irritation.

In any case, no final judgment is possible at present as to the role played by the ductless glands in the pathogenesis of glaucoma. Experiments are much to be desired that would forge a binding chain of evidence between such disconnected links as endocrine activity, vagotonia, sympatheticotonia, protein sensitivity, acidosis and calcium deficiency as exemplified in asthma, hay-fever,

rhinorrhoea, urticaria, angioneurotic edema, glaucoma, and migraine and epilepsy.

Dr. W. S. Franklin suggested that the injection should not substitute operative measures which accomplish their object in a large number of patients.

Dr. Otto Barkan—We have tried glandular extracts in a number of cases of glaucoma without results. In one case of glaucoma associated with a vascular neurosis, hypodermic injections of adrenalin lowered intra-ocular tension for from several hours to a day. We have found that subconjunctival injection of adrenalin is particularly useful in iritis with secondary glaucoma, inasmuch as it lowers tension and dilates the pupil at the same time.

Dr. George Hosford—We have had essentially the same results as Dr. Pischel on cases at the University of California clinic.

Dr. Pischel, in closing, stated that injection is no substitute for operations in glaucoma, but is a great help for the control of glaucoma in its different stages, and also as a preliminary to operation or to examination.

3. Paper: "Further Observations in the Use of Thyroid in Incipient Cataracts"—George N. Hosford.

Synopsis—Twenty-four patients with senile cataract of various degrees of maturity were treated over a period of from three to twelve months with thyroid substance (Armour) in doses of from 3 to 6 grains.

Fifty per cent of the patients showed improvement of 0.1 or more. Thirty-seven and one-half per cent showed no change, while 8 per cent became distinctly worse. One case improved in one eye and became worse in the other. The greatest improvement obtained was from 0.3 to 0.6. This was in a man of thirty-eight, who took large doses over a long period. In one patient not included in the above series, a man of forty-seven, with incipient cataract in both eyes, had a needling done in the left eye six months before we saw him. The absorption of lenticular material seems to have been remarkably accelerated by thyroid substance in doses of 3 to 6 grains per day. In two patients with secondary cataract, the results were negligible. We intend now to try pure thyroxin and also parathyroid substance. Discussion was opened by Dr. W. J. Kerr.

Dr. Hans Lisser stated that Hosford's admirable paper deserves hearty commendation. No flamboyant claims are made; it exemplifies a sincere effort to arrive at truth by thorough methods of study. Determinations of the metabolic rate are desirable if for no other reason than to discover in which patients an actual thyroid deficiency is being supplemented by the thyroid extract administered. In those patients with normal rate, the beneficial action would have to be interpreted as that of a tissue stimulant, a metabolic tonic. We have by no means exhausted the possibilities of thyroid therapeutics as a general tonic, in which respect it is far more potent than iron, quinine, or strychnine, though it must be used with exceeding care. I am not inclined to think that any of the improvement noted was due to a possible admixture of parathyroid material. We are only certain of one clinical entity due to parathyroid insufficiency, namely, tetany, and there are no authentic instances where this condition has been relieved by the use of any of the commercial parathyroid preparations available. Parathyroid extracts in the treatment of tetany are in the same position that pancreatic extracts were in the treatment of diabetes before the discovery of insulin. Their use was logical, but they were impotent. When an active parathyroid extract is discovered its trial in the treatment of cataract will be indicated, since cataract is an important complication of tetany, and has been experimentally produced in animals (Erdheim) by removal of the parathyroids.

It is indeed true that trophic degenerations affecting the skin, hair, teeth, nails and lens are characteristic of senility, quite in the same way as are thickenings of arteries and degenerative changes in kidney, brain, and heart. Is it sound reasoning to assume that these gradual gradations of decay are due to endocrine disease and, therefore, amenable to organotherapy? Is it not more reasonable to believe that the ductless glands are sharing in the aging process in the same degree and simultaneously with all other tissues of the body? Is it sound practice to attempt to whip the weary old horse into a ridiculous

and dangerous gallop? Might it not prove to be his last spurt when he might have walked for some time longer?

This is no criticism of the use of thyroid extract in cataract except as it may suggest a distinction between the true senile cataract of good old age and the cataract of a premature senility. And herein lies the kernel. A premature senility, a cataract between 30 and 50 years of age, is quite a different matter. Such premature decay is most likely due to disease processes of thyroid, pituitary or gonads, that have aged the glands before their time. Here most certainly do we have indication for glandular therapy. Meanwhile a judicious trial of thyroid extract in the treatment of cataract, in conservative dosage, under very careful supervision, may prove worth while, as indicated by this excellent preliminary paper. Both Dr. Kerr and Dr. Shepardson deserve credit for their important share as physicians in aiding the study and observation of these patients.

4. Paper: "Submucous Resection Without Packing"—Rea E. Ashley.

Summary—Since operation of resection of the nasal septum was first described, various methods and materials have been used to keep the flaps in apposition and to prevent hematoma.

The three most popular methods are: 1. Packing (innumerable materials have been used). 2. Use of metal clips. 3. No packing whatever.

This paper deals with the last method, giving technique and reporting eighty cases done without packing.

Summary—1. It is not necessary to pack. 2. Results are just as good or better without it. 3. Convalescent time is cut down. 4. Patient is much more comfortable. 5. There is less danger of complications.

Dr. Wallace Smith stated that he always uses Bernay Simpson tampons. He sees no particular advantage in not packing.

Dr. A. C. Gibson agrees with Dr. Ashley. For three years he has not packed a nose except in one case of an anomalous artery crossing the sphenoid. Other discussants were Drs. Pischel, Fletcher, Price, and Ashley.

St. Joseph's Hospital Staff, San Francisco, was addressed on January 14 by Sister Dionysia, directing dietitian, on "The Aims of the New Dietetic Department." Dietetics was declared a factor in preventive medicine and food idiosyncrasy discussed. Investigative methods described were dietary study, respiratory quotient, carbon and nitrogen determination and calorimetric estimation—the last being stressed—and all showed striking consistency. Two thousand to 3300 calories daily, according to muscular exercise, was declared sufficient. Construction of diet is determined by the patient's weight, height and condition, and on a maintenance diet there is some gain in weight. Preliminary laboratory examinations and a test diet are required. Special diabetic, nephritic and other therapeutic diets are ordered by the doctor and the dietitians care for it in the diet kitchen. The tray is carried to the patient by the nurse in the diet kitchen, nothing being added by any Sister or nurse. The foods are weighed before and after eating. New diet charts were explained, the principle being to individualize the dietary, as is done for each patient in any other branch of medicine and surgery. A stubborn case was quoted in which the patient could not be made sugar-free until it was discovered that he was taking sugar-coated pills.

Dr. R. M. H. Berndt presented a case history of a patient with nephritis and cardiovascular complications.

Dr. E. C. Fleischner spoke on "Indications and Contra-indications for Tonsillectomy." He divided children into two groups—those under 5 years and those over, stating that in the younger the lymphatic tissues of the tonsils are more active in developing immunity, and there should be more definite reasons for removal. Redness of the anterior pillars and small granulations at the reflection of the mucous membrane from the anterior pillars to the uvula are definite signs of disease and disappear after tonsillectomy. Simple hypertrophy is often nature's way of increasing the bactericidal power of the tonsil and, unless it obstructs breathing, should not prompt removal. Deep abscesses in the tonsil are indications for removal, as are also involvement of regional lymph glands and a

history of diseased tonsils, malnutrition without other cause, otitis media, repeated upper respiratory inflammation, chorea, erythema nodosum, acute arthritis, if teeth are good, and repeated follicular tonsillitis or quinsy. Do not operate, ordinarily, during acute diseases, even cervical adenitis. An exception is a monarthrititis—if teeth are good. When the resistance is lowered by acute lesions, tonsillar infection tends to cause septicemia, while after the resistance is regained the lesions remain localized. Endocarditis, if chronic and not due to other focus, especially with glands, and acute hemorrhagic nephritis following tonsillitis after the nephritis has subsided, justify tonsillectomy. Under 5 years tonsillectomy is in order with repeated otitis media or tonsillitis, acute arthritis (monarticular), and obstruction to breathing. Simple hypertrophy, even with lymph glands, should be delayed to a later age, when the function of the tonsil is not so necessary. Roy Parkinson opened the discussion and advised tonsillectomy for diphtheria carriers and hoarseness also, and compared the merits and demerits of the operation. Ethan Smith gave some of the failures from it in joint lesions. Harold Wright touched upon tuberculosis as an indication and contra-indication. E. C. French mentioned asthma with negative protein reaction as an indication. He also reported upon St. Joseph's Hospital clinic, and H. B. Dixon stressed the need of social service for it.

The program for February 11 follows: "Post-operative Cardiac and Pulmonic Therapy," A. W. Hewlett; and "Treatment of Surgical Post-operative Complications," C. A. Walker.

Sisters Appreciate Doctors' Aid—The Sisters of St. Joseph's Hospital deeply appreciative of the favor shown them by the hospital staff in voluntarily assisting them in giving the hospital publicity in the advertising pages of CALIFORNIA AND WESTERN MEDICINE and Better Health, wish to express their gratitude to all for their manifestation of loyalty to St. Joseph's Hospital. The Sisters hope that the doctors' work may be blessed with success throughout the year, which they feel will be a happy one for all.

Southern Pacific General Hospital Clinical Meeting (reported by W. T. Cummins, secretary)—The regular monthly meeting was held at the General Hospital, San Francisco, on Wednesday, January 7. Subject: "Diseases of the Thyroid."

1. Medical Aspect—Hans Lisser illustrated a number of cases of thyroid disease, including goiter, myxedema, etc., and spoke of specific medication in each, with especial reference to the effect of iodine in goiter. The associated pathology of other endocrine tissues was discussed. Obesity in pre-adolescent life was commented upon as being probably always of endocrine origin.

2. Surgical Aspect—Wallace I. Terry spoke of the early determination of goiter districts in consequence of the deficiency of iodine in the formation of the superficial stratum of the earth's surface. He reviewed the technique of operation and discussed the different phases of the pathology of the thyroid gland, including hyperplasia, adenoma, carcinoma, and thyroiditis. Much stress was laid upon the value of iodine, as Lugol's solution or some other assimilable iodide, in conjunction with operative procedure.

3. Projectoscopic Demonstration of Specimens—Edwin I. Bartlett demonstrated a large number of slides illustrative of the various types of thyroid disease. The importance of the consideration of the gross pathology with the microscopic was emphasized. The infrequency of sarcoma was noted.

❧

SANTA BARBARA COUNTY

Santa Barbara Cottage Hospital—The fourth annual clinic day of the Santa Barbara Cottage Hospital was given by the staff on Monday, January 12, 1925. The morning session, from 8 to 12, was devoted to an Eye, Ear, Nose, and Throat Clinic, and also a Major Surgical Clinic. After a luncheon, served at the hospital, the Medical Clinic held an afternoon session in the new staff room.

An interesting program, following the annual dinner of the Santa Barbara County Medical Society at the Hotel Carrillo, completed the day.

YOLO COUNTY

Yolo County Medical Society (reported by John D. Lawson, secretary)—The quarterly meeting of the Yolo County Medical Society was held in the reception room of the Clinic Building, Woodland, on January 6.

The following officers were elected for 1925: President, Thomas E. Cooper, vice-president, Moses W. Ward; secretary-treasurer, John D. Lawson; delegate, Fred R. Fairchild; alternates, W. E. Bates and M. W. Ward. Dues were fixed at \$12.

E. Eric Larson, associated with the Mayo Clinic for the past four years, is now connected with the Woodland Clinic staff, in the Department of Urology and Surgery.

The Woodland Sanitarium has just acquired a half block of property facing the present building on the south. Plans for further expansion are now under consideration.

H. D. Lawhead was reappointed County Physician and Health Officer for 1925.

At a special meeting held October 23, 1924, the following motion was unanimously adopted: "All patients are to be charged regular office rates for prophylactic smallpox and diphtheria measures, except indigent cases, which are to be cared for by county health officers, with the assistance of members of the society." There was considerable discussion on this subject, in view of the large amount of free prophylactic treatment which has been given previously, it being felt by the members that the physicians should give no more free service, except in indigent cases, than in any other type of medical practice.

Clinics have been inaugurated by the Woodland Clinic staff: Children of pre-school age, Tuesday, 2 to 4; school age, Thursday, 2 to 4; adult free clinic, Wednesday, 2 to 5.

Doctors C. H. Fairchild and Fred R. Fairchild are on a two months' leave of absence. Both are engaged in special work in the East and Middle West.

The monthly clinical conference of the Woodland Clinic was held in conjunction with the quarterly meeting of the Yolo County Medical Society. The following papers were presented: "Treatment of Sprains, Bruises and Minor Injuries"—W. E. Bates; discussion opened by E. Eric Larson. "The Use of Nitrous Oxide in Obstetrics"—N. M. Salter; discussion opened by W. J. Blevins. "An Unusual Case of Pellagra"—F. P. McManus; discussion opened by J. Edward Harbinson.

Don't wait for your county secretary to dun you for medical society dues. They should be paid now.

CHANGES IN MEMBERSHIP

New Members—Eugene H. Hull, J. A. Patterson, San Bernardino; Edgar C. Lee, San Diego; Walter E. Whalen, K. S. Davis, Zoe M. Ruth, Los Angeles; D. L. Burgeson, La Habra; Reginald F. Grant, A. M. Moody, Isabella M. Clinton, San Francisco.

Transferred—Fred W. Loring, Albert G. Bower, from Fresno County to Los Angeles County; Eugene W. Whitney, from Los Angeles County to San Diego County; William R. Dorr, from San Francisco County to Riverside County.

Deaths—Bridge, Norman. Died at Los Angeles, January 10, 1925, age 80. Graduate of Northwestern Medical School, Chicago, 1868, and Rush Medical College, Chicago, 1878. Licensed in California in 1891. Dr. Bridge was a member of the Los Angeles County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Joseph Louis Howard. Died at Honolulu, December 29, 1924, age 55. Graduate of Cooper Medical College, California, 1900; Royal College of Surgeons, England, 1902; and Royal College of Physicians, London, 1902. Licensed in California in 1900. Dr. Howard was a member of the San Francisco County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Lewis, J. Perry. Died at Honolulu, December 29, 1924, age 58. Graduate of the General Medical College, Chicago, 1895. Licensed in California in 1896. Dr. Lewis was a member of the San Diego County Medical Society,

the California Medical Association, and a Fellow of the American Medical Association.

McArthur, Newbern Turner. Died at San Francisco, December 31, 1924, age 42. Graduate of Cooper Medical College, California, 1912. Licensed in California, 1915. Dr. McArthur was a member of the Napa County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Sewall, Charles Albert. Died at Los Angeles, January 7, 1925, age 75. Graduate of the University of Pennsylvania School of Medicine, Philadelphia, 1872. Licensed in California in 1899. Dr. Sewall was a member of the Los Angeles County Medical Association, the California Medical Association, and the American Medical Association.

New Health Officers—John Anthony Azevedo, M.D. (Stanford, 1923) of Hayward has been appointed Public Health Physician of Alameda County. Doctor Azevedo is licensed to practice medicine in California, but is not a member of the California Medical Association.

Mr. Frank B. Wilcoxon has been appointed Public Health Officer of Pacific Grove. So far as we know, Wilcoxon is not licensed to practice.

Harry J. Willey, M. D. (Univ. Med. Coll. Mo., 1904), of Porterville has been appointed Public Health Physician of that city. Doctor Willey is licensed to practice medicine in California, and is a member of the California Medical Association.

George Parrish, M. D. (Missouri Med. Coll., 1894), of Portland, Ore., has been appointed Public Health Physician of Los Angeles. Doctor Parrish has been licensed to practice medicine in California. He is a member of the Oregon Medical Association.

J. PERRY LEWIS, M. D.
1866-1925

When word was received in San Diego during the holiday week that Doctor J. Perry Lewis had died in Honolulu, where he had gone with Mrs. Lewis and friends for

a brief vacation, it saddened the hearts of hundreds throughout Southern California, for Doctor Lewis was a popular and beloved man.

Temperamentally, he was an ideal physician and brought to bear upon the problems of a heavy practice a fund of rare qualities not acquired in college. Graduating in Chicago in 1895, he came to California the following year and has practiced continuously in San Diego since that time. Possessed of a genial and attractive personality, the outward expression of a warm Christian character, he rapidly became prominent in his profession and was soon confronted with the problem of how to take life more easily. For several years he had endeavored to lighten the burden by limiting himself to the specialty of diseases of the nose and throat; yet he had built up such a multiplicity of connections—social and professional—that this but partially lightened his load. He made time for golf—his chief recreation—which undoubtedly helped to keep him physically fit to “carry on”; but no constitution could forever withstand such demands upon it, and he died a martyr to his profession as surely as any more spectacular hero. He was an ex-president of the San Diego County Medical Society, being in office when last that organization entertained the state society. His quiet courtesy and pleasing greeting will be remembered for many a day by his fellow-members of the local profession.

R. P.

STIMULANTS, DEPRESSANTS, HUMOR

Apropos of an editorial in the last number of the Journal entitled “Doctor, Heal Thyself,” the epitaph on the slate tombstone of a Dr. Preston in the Colonial graveyard in Keene, New Hampshire, may interest you: “He healed others, himself he could not.”—Emmet Rixford.

A dorky called at a hospital the other day and said: “I came to see how mah friend Joe Johnson am getting along.”
“Why, he’s getting along fine,” the nurse answered; “he’s convalescing now.”
“Well,” said the dorky, “I’ll jest set down and wait till he’s through.”

“As an alumnus of our State Medical School I wish to enter a vigorous protest against some of the advice being given in a health service said to be conducted by a department of our school. I particularly resent the propaganda advising parents to take their children to “psychologists,” “child guidance clinics,” “habit clinics,” in preference to doctors who have been taught and licensed to practice.—San Francisco.

The Pathology of Osteopathy

“But, my dear, aren’t these osteopaths rather—I mean to say—intimate in their manipulations?”
“Oh, yes. I had to become engaged to him for the course of treatment!”—Judge.

“... I am enclosing a clipping from the so-called health column of a San Francisco newspaper. The author seems to think much of Bernarr McFadden, osteopaths, chiropractors and Christian scientists as doctors. Can anything be done about it?”—Sacramento.

Note—The important item of the clipping makes a comparison in mortality statistics from influenza as follows:

“The M.D.’s lost one case in sixteen, the osteopaths one case in 128, the chiropractors one in 300 approximately, while Christian scientists and naturopaths lost an even smaller percentage of their cases. I will not vouch for the authentic accuracy of these figures as given, but I know that these ratios obtained approximately, and I know that the more doping, serumizing, feeding and ‘treating’ of any kind given in acute diseases, the higher will be the death rate.”

No Competitors

“Who done make de best cord tire?”
“De Lord.”
“De Lord?”
“Sure! He done makc de spinal cord. Dey last a lifetime.”

“... the disgusting propaganda widely published recently as ‘news’ about the bloodless radio knife said to be so effectively employed at the U. C. Hospital is enough to make every doctor who has studied at that institution blush for shame.”—Oakland.

Utah State Medical Association

SOL G. KAHN, Salt Lake City.....President
WILLIAM L. RICH, M. D., Salt Lake.....Secretary
J. U. GIESY, 512 Felt Bldg., Salt Lake City,
Associate Editor for Utah

WHEN IS AN AD NOT AN AD?

The poor we have always with us. In that respect the poor are not unlike the doctor who tries to chase the devil of the dollar around the ethical stump. Shaving the line closely, he eschews a professional card in a daily paper with uplifted palm of horror, but he has a card on a hotel register, sandwiched between that of a laundry on one side and a popular-priced eating joint on the other. He—purely as a matter of fraternity—runs a similar card in the paper of some lodge or similar organization, and sits back to await, or at least to hope for, results. Ethically, maybe he can still get away with it. I don’t say he can’t. But in this day and age it smacks a bit of a mental state that should not characterize medicine of the highest type. And medicine should be high today, higher than ever in its aims and ideals. Long, long years ago it was said, “By their fruits ye shall know them.” And the best “ad” any medical man can use in his walk of life is *works*—the results of his endeavors to deserve the title he wears. Then may he be proud to wear it; then may it be to him a badge of distinguished service; then will he find little need to advertise in the commonly accepted understanding of the word.

PEDIGREED BUNK

Without taking a leaf out of Uncle Billy’s Whizz Bang, the phrase is not without application to the medical profession of the present day, and is largely the cause of the flourishing condition of the cults. Let us stop and take an inventory of ourselves. Barnum remarked that the public liked to be fooled. That’s bunk also, of course. The truth is that the public doesn’t like to be fooled, but that it doesn’t always know that it is being fooled, because the public doesn’t always know what it’s all about.

We as a profession are seeking to do good work. Nobody can truthfully challenge the fact, but, in our enthusiasm over our own advancements, our own investigations and endeavors, we are overlooking in a large measure the very thing that a few years ago made the old family doctor what he was—a man with a hold on his clientele, next only to that of the priest—friend and advisor as well as medical servant—wise man, kindly man, to be looked up to and given full trust.

Nowadays the average man at least tries to use his head. He likes to know what is being done to him or for him, rather than treated too much as an erudite problem in metabolism, which is a word conveying nothing to his intellect. Here it is that the cults get in their work and sell their pedigreed bunk. They at least make him feel that they are appealing to his intelligence. The assumption may be flattery, of course, but flattery is one way of selling the prospective buyer, none the less. Hence, it’s time that we as a profession got back to the old-time basis

of understanding co-operation between doctor and patient, insofar as the ideal may be obtained in the individual case.

Wise looks and reticence may appeal to the occasional man. He may be content to go forward in a childlike faith. But the majority will respond far better to an understandable explanation of what is being done for him, a brief and comprehensible exposition of what the medical profession is today actually doing for the race. Surely, we may tell of the real, the far-reaching results of our own work and progress, as well and as advantageously as the cults with their pseudo-science camouflaged in words.

Let's get back into the personal contact with our patients on the personal basis, drop the oracular attitude and sell ourselves as our grandfathers sold themselves and their profession to the multitude of loyal and trusting clients whom they served. After all, it is the personal element, the personal contact, that lies back of all real human associations from the cradle to the grave. Let's fight the pedigreed bunk of the cults with the living truth. Let's spend a few more words on the individual patient to win his intelligent, understanding confidence.

Utah Notes (reported by J. U. Giesy, associate editor for Utah)—The banquet scheduled for December 29, in honor of Doctor Salathiel Ewing, one of the oldest physicians in the state, was regrettably canceled, owing to the poor health of Dr. Ewing. He is past 90 years of age, and is in the hospital at present.

R. R. Hampton, councillor for the Second District, has resigned, on account of ill health. J. C. Landenberger of Salt Lake City was appointed by the council to fill Dr. Hampton's place.

Dr. William Rich returned from the meeting of the secretaries of the A. M. A. In his report he says:

"The program committee has asked me to give a brief report of the transactions of the last annual meeting of the secretaries of the Constituent State Medical Association held in Chicago, November 21 and 22.

"There were present thirty-seven state secretaries; twelve editors of journals and officers of the American Medical Association and board of trustees. The most important paper was presented by Frederick C. Warnsluis, secretary of the Michigan State Medical Association and speaker of the House of Delegates, who outlined a definite plan of action for 1925, which was approved by the board of trustees. Briefly, the plan was to formulate a better understanding of, first, The American Medical Association; its history and development; its plan of organization; Constitution and By-laws; its administration features, including its work and achievements; and the service it renders to the physician; and explanation in detail of its publications; of the requirements of fellowship and the benefits of fellowship. Second, the state society organization; its activities; its membership, qualifications and benefits. Third, the individual's responsibility to county, state and national organization; to fellow-practitioners; to the community and to humanity.

"To briefly review some of the things brought out in this paper and its discussion, one must begin with the unit of the national organization, the County Medical Society, of which there are 3047 in the United States. Some of these units have as few as four or five members and some as many as several hundred. But, each has certain officers; board of censors; various committees and members, and a constitution and by-laws. These units go to make up the various state associations. The state associations are organized the same as the county society, but have, in addition, a House of Delegates and councilors, representing councilor districts. The function of the council is to act as the executive body of the association between meetings of the House of Delegates.

"Its function is to aid in co-ordinating the work done by the county societies and through the work of its various committees to keep in touch with the needs of the

profession and humanity in the state. To hold annually a scientific meeting available to all members of the component county societies of the state and to transact such business as is vital to its well-being.

"In addition most of the state organizations publish a state journal, in which papers from the various county societies and the proceedings of the annual meeting, including the scientific papers, appear. The smaller states join together and two or three or four are represented by one journal, as is the case with us in Utah.

"The national organization is similar to the state organization and has its headquarters near the center of population. Like the state, it has its officers and board of trustees instead of councilors, a House of Delegates and various committees and bureaus and section officers, Fellows and members. It publishes and edits several scientific journals, owns its own buildings and equipment, which is worth over \$1,000,000. It is the largest and most powerful organization of medical men in the world. It has a membership of 90,000 members, 55,000 of whom are Fellows. It has a reserve fund of over three-fourths of \$1,000,000, and we ought to be proud of our membership in it.

"Probably the greatest piece of constructive work performed by the national organization is the work done by the Council on Pharmacy and Chemistry. Nostrums of a few years ago of the rank type have mostly disappeared. The aid of the council is now sought by investigators and manufacturers before they attempt to offer any medical product to physicians. The problem of this department is now more concerned with biologic products as therapeutic agents. This department, through the chemical laboratory, has aided greatly in the standardization of drugs. The activities of the propaganda department are far greater than at any time in its history. Thousands of letters from laymen, lawyers and doctors are received and answered by this department each year. This department has also conducted a clipping bureau and is furnishing articles to many magazines and journals whose subscriptions total over 1,000,000. It has furnished such journals with articles from Hygeia, and you will find them appearing regular every month in certain magazines. It has furnished educational posters, stereopticon slides for public health work in schools and colleges. It has also given the committees on scientific research certain grants in money to various institutions and physicians to aid in research. Sixty-one grants, amounting to \$1500 for 1923.

"The Bureau of Legal Medicine, which was created two or three years ago, is now in full running order and can give to county or state associations legal advice on medical subjects. This department, through Doctor Woodward, keeps the various state associations informed regarding national legislation affecting the profession. Like the state association, the national body holds an annual meeting in some city selected by the House of Delegates. Its scientific meetings are divided into sections representing the various specialties. All members may attend these meetings, but none but Fellows may hold office or participate in the deliberations of the assembly. It is possible some of you may not clearly understand the difference between fellowship and membership. If you join your county society you automatically become a member of the state association and the American Medical Association, but no part of your dues goes to the A. M. A. Therefore, you are not supporting in any financial way the national organization. But if you subscribe to any one of its publications a part of that subscription will go to fellowship dues, providing you make such known by filling out an application for fellowship. Many of you probably have the opinion that you must subscribe for the A. M. A. journal. That is not necessary, providing you subscribe for some other journal, such as the Archives of Otolaryngology, American Journal of the Diseases of Children, Archives of Neurology and Psychiatry; Archives of Internal Medicine, Archives of Dermatology and Syphilology, and Archives of Surgery.

"The national organization is also aiding the profession by way of educating the public through the public health journal, Hygeia. This seems to be not greatly appreciated by the profession, as only 14,000 out of 90,000 are subscribing for it. The journal has a circulation of about 30,000, and is published at a loss of over \$15,000 a year. This little journal was gotten up to fight our battles with humanity, and gives us a better standing in the com-

munity. It will help to keep away state medicine and help us to get better and more just laws. It will help us to make the cults impossible. It is excellent reading for any physician. It should be kept on the library table in every physician's and dentist's waiting-room. It should be in the hands of every school teacher, and some one of our profession should be present at every state teachers' convention to speak of its merits.

"The national organization will soon have completed arrangements to give post-graduate work to our county societies. The details have not been worked out, but the board of trustees has ordered the officers to prepare for it. Periodic health examination was urged by Dr. Albert E. Bulson. I want to say that if the county society does not perform this duty to the public, lay organizations will hire a physician for a comparatively small salary and make the examinations at a good profit for themselves. So we must keep this in mind and be prepared to take it up.

"The Utah State Industrial Commission affairs stand out as a bright and shining example to other states. You are all familiar with it, so the details will not be gone into. The board of trustees authorized the business manager of the association to provide an official automobile emblem that may be copyrighted and used by members of the A. M. A. only."

M. M. Critchlow, secretary of the Salt Lake County Society and members of the United States Veteran's Bureau of Salt Lake, has gone to U. S. V. Hospital No. 98, Castle Point, N. Y., to attend the Government School of Tuberculosis. A class of sixty men will be in attendance at this intensive course of instruction in tubercular conditions for a period of two months. During Dr. Critchlow's absence Lester J. Paul, director of the local Veterans' Bureau, will act as secretary of the Salt Lake County Society.

The state legislature is now in session. We understand that a bill is being prepared for presentation, giving the chiros the right to treat all industrial injury cases by the well-known procedure of twisting or otherwise assaulting the spine. If the legislature passes the thing, it will be one of the heaviest blows to the chiros ever dealt in the state. Time is a thing that both reveals and cures many things. In other words, it "adjusts" a great many badly adjusted affairs.

It might be of interest to the members not in the local vicinity to know that Salt Lake County Society has done much in the Industrial Commission activities, thereby helping to create a favorable feeling between the Commission and the profession in the state. The state society has been in the habit of appointing a board of three members to act as a board of review in association with the Commission for the purpose of passing on cases before the Commission for settlement. These members are necessarily drawn from the local society because of expediency due to their local residence, and all men serve without compensation, being appointed in rotation from the local society ranks. All this has resulted in a very friendly attitude, and we believe that it has done much to secure just settlements and general satisfaction during the last few years. This is a real service which those who serve on the board are rendering both to the profession and to the social structure of the community itself.

At this time the erection of an eight or ten-story professional building in Salt Lake City seems assured. The building committee has opened the books for subscriptions from the profession, and are meeting with encouraging success. Such a building is bound to come and will fill one of the greatest professional needs.

Seymour B. Young, M. D., 1837-1924—Dr. Seymour B. Young, pioneer physician of Utah, died at his home December 15, 1924. He had been in poor health for several months.

Doctor Young was born in Kirtland, Ohio, October 3, 1837, son of the late President Joseph Young and Jane Bicknell. His father was the elder brother of President Brigham Young.

He was graduated from the Medical College, New York University, in 1874, receiving the bronze medal as third honor student of his class out of a total of 208.

Dr. Young was probably the oldest college graduate in the state of Utah, a record in which he took great pride. His success as a physician is attested by the fact that hundreds of people tell of the great worth of Dr. Young

in years gone by as a man of medicine. No physician ever administered greater comfort to his sick than he did. His very spirit was one of happiness and hope.

James Monroe Dart, 1840-1925—Dr. James Monroe Dart, one of Utah's oldest practicing physicians, is dead, at the age of 85, at his old home in Roxbury, N. Y.

Dr. Dart came to Salt Lake City in September, 1881, from Elizabeth, N. J. At that time he had already been graduated for years from the College of Physicians and Surgeons in New York City, following that with studies in homeopathy, and had been practicing for a considerable time. He opened offices in Salt Lake City and soon enjoyed a large practice.

In addition to being a brilliant medical man, Dr. Dart was declared to have been unusually learned along other lines, having a vast fund of information on many subjects. Perhaps the outstanding thing about the decedent was his love for music. His hobby was collecting old violins. He was regarded as an expert on rare violins and corresponded with collectors of this instrument in all parts of the world. He always had a number of instruments in his possession and, while not a brilliant performer himself, could play creditably.

Weber County Medical Society (reported by R. L. Draper, secretary)—At the meeting of the Weber County Medical Society held at the Reed Hotel, Ogden, December 16, 1924, F. K. Bartlett presiding, the following officers and delegates were elected for the ensuing year: President, E. M. Conroy; vice-president, W. R. Emmett; secretary-treasurer, R. L. Draper. Delegates: Eugene H. Smith, Ezra C. Rich, E. P. Mills, F. K. Bartlett. Alternate delegates: Henry W. Nelsen, A. Z. Tanner, G. G. Moyes, L. S. Merrill.

Minutes of the Salt Lake County Medical Society (reported by L. J. Paul, acting secretary)—The regular meeting of the Salt Lake County Medical Society was held at the Salt Lake Chamber of Commerce, Salt Lake City, January 12, 1925, President John Z. Brown presiding. Members, present, 41; visitors, 3. Clinical cases, 2.

Burtis Robbins presented two clinical cases, showing the results of his plastic operations on the face with a unique apparatus designed to cover the defects caused by the loss of one eye. The apparatus is constructed attached to a pair of spectacles. He was assisted in its construction by Dr. Creed Hamand, dentist of this city.

The scientific program consisted of a paper by Joseph H. Peck on "Infectious Jaundice in Tooele County." He effectively outlined the subject from his own practice, showing the infectious nature, the great loss of time experienced by school children, and stated that it was endemic in Tooele County. No fatalities. Discussion by J. U. Giesy, S. D. Calonge, and H. S. Scott.

William L. Rich, secretary of the state association, gave an excellent report on the meeting of the secretaries of the constituent components of the American Medical Association. General discussion followed on the points mentioned in his report by S. H. Allen, T. F. H. Morton, E. F. Root, A. A. Kerr, S. D. Calonge, E. M. Neher, and James P. Kerby.

The subject of a full-time physician on the payroll of the state for work with the Industrial Commission was discussed at some length. It was decided, however, that our present plan of rendering free consultation and assistance to the State Industrial Commission was the most satisfactory. A motion by Fred Stauffer, to the effect that members of our society be paid for their services with the Commission, was lost.

Applications for membership were received from Alfred Blumberg and Edward Day and referred to the board of censors.

The following committees were appointed for the coming year:

Community Clinic—George W. Middleton, chairman; A. J. Hosmer, E. M. Neher, William L. Rich, Willard Christopherson, F. E. Straup.

Building—Fred Stauffer, chairman; E. F. Root, W. R. Calderwood, M. M. Nielson, H. P. Kirtley.

Public Health and Legislation—Sol G. Kahn, chairman; S. D. Calonge, T. F. H. Morton.

Library—W. R. Tyndale, chairman; B. E. Bonar, F. J.

Curtis, E. D. LeCompte, Joseph E. Jack, F. B. Steele, F. A. Goeltz, R. T. Richards.

Dr. Fred Stauffer reported on the subject of a banquet for Dr. Salathiel Ewing, who is now receiving treatment in a local hospital. It was moved by Dr. Stauffer that the money received to finance this banquet for our oldest honorary member be donated to Salathiel Ewing by the individuals contributing. Motion carried. The secretary was instructed to receive the contributions of all members willing to so divert their donations in this manner.

California Association of Physiotherapists (reported by Beret Stenvig, local secretary)—The uses of the mercury quartz lamp formed the subject of the meeting of the San Francisco branch of the California Association of Physiotherapists held on December 10 in the Medical building.

Dr. B. F. Deering spoke on its use in children's diseases, giving reports and conclusions on his work at the children's clinic at University of California Hospital. Bronchial conditions, asthma and undernourished children were among the cases which he stressed as showing interesting results from the use of the mercury quartz lamp. During the course of the treatments in all cases a close check is kept on these three points: weight, appetite, and relief of symptoms. A marked increase in weight and appetite has been gained in almost all cases. The general experience has been an improvement of symptoms after six or eight weeks of treatment. While no permanent and definite cures under the quartz lamp treatment have yet been established with asthma, there has been a decrease in the severity of the attacks and a decrease in the number of colds. His conclusion is that the mercury quartz lamp assists very materially in building up the child's resistance, a factor of great value in combating conditions of that type.

Miss Beulah Rader of the Marine Hospital, with a wide experience and a variety of patients from which to draw her conclusions, talked on quartz lamp technique and gave case reports on patients treated with the lamp.

The meeting of January 14 was devoted to a symposium on arthritis, with the discussion from three different standpoints. Dr. William J. Kerr spoke from the medical standpoint, Dr. H. H. Markel from the orthopedic, and Dr. Thomas J. Crowley from the electrotherapeutic.

Dr. Kerr gave a wide and interesting classification of the various types of arthritis with the medical treatments indicated. In addition, the treatment consists in seeking any foci of infection and removing it if possible, increasing the nutrition if underweight, and reducing if overweight.

Dr. Markel, in speaking from the orthopedic standpoint, gave detailed descriptions of all the various casts and methods of applying for inducing immobilization of a joint to relieve the pain. He also described some operative procedures where such were indicated and the methods and positions for ankylosing a joint when such was desired.

Dr. Markel and Dr. Kerr were of the same opinion, that physiotherapy, in the form of heat, massage and manipulations, was of great value in the treatment of arthritis after the stage of acute inflammation and pain had passed, to increase the nutrition of the tissues and prevent deformities and ankylosis. Dr. Markel emphasized the fact that physiotherapy in such cases should be employed with care and that manipulations preferably be given once only during the treatment and as much within the limits of pain as possible.

Dr. Crowley gave a different slant on the subject by discussing diathermy and galvanism. Both are given only after the chronic stage is reached. Diathermy is given daily for one-half hour, its benefits being in a hyperemia within the joint which results in increased metabolism. With galvanism, the effects are chemical. The positive pole is usually used because it is sedative in action and will introduce chemicals into the body at a given point. Along with this treatment he stressed the importance of accelerated elimination.

Nevada State Medical Association

W. M. EDWARDS, M. D., Mason.....President
CLAUDE E. PIERSALL, M. D., Reno.....
Secretary-Treasurer and Associate Editor for Nevada

Washoe County Medical Society (reported by Henry Albert, secretary)—The Washoe County Medical Society met in regular session in the rooms of the Chamber of Commerce January 13, 1925, President Vinton A. Muller presiding.

Program—Henry Albert presented a paper on "The Newer Knowledge Relative to the Etiology and Prevention of Scarlet Fever." He discussed especially the Dick test and immunization by means of toxin of the specific streptococcus. The paper was discussed by Tees, Morrison, Pickard, Lewis, and Robinson.

J. A. Fuller presented a paper on "The removal of Foreign Bodies From the Eye." In addition to the common forms of foreign bodies, he emphasized especially certain ones of local Nevada interest, such as sawdust and cactus spines. The paper was discussed by Robinson, Barrows, and Brown.

H. J. Brown presented a paper on "Post-Operative Treatment." Emphasis was placed on enemas instead of purging doses of castor oil. The treatment of shock, paralytic ileus and retention of urine was also considered. The paper was discussed by Lewis, Caples, and Bath.

Unfinished Business—Dr. M. A. Robison mentioned what progress was made in securing data as to the value of the work done under the Sheppard-Towner Act. He also stated that the defects in the hospital bill which passed the last legislature, but which was declared unconstitutional, had been remedied, and that the corrected bill would be again introduced in the coming session of the legislature.

New Business—The following visiting staff (to serve for one year) for the State Hospital was appointed by the president: Donald MacLean, surgeon; S. K. Morrison, physician; J. L. Robinson, otologist and rhinologist; C. E. Piersall, roentgenologist; W. L. Samuels and M. A. Robison, anesthetists.

Attendance—Members: Albert, Barrows, Bath, Brown, Caples, DaCosta, Fuller, Lewis, Morrison, Muller, Pickard, Piersall, Robinson, Robison, Servoss, and Tees. Guest: Professor Peter Franssan.

New Committees of Nevada Medical Association (reported by C. E. Piersall, associate editor)—The following appointments were recently made by the president-elect of the Nevada State Medical Association:

Membership—B. Brown, Yerington; A. C. Olmsted, Wells; C. C. Bullette, Las Vegas.

Judicial—M. A. Robison, Reno; R. A. Bowdle, Ely; A. J. Hood, Elko; A. R. Craig, Tonopah; Horace J. Brown, Reno.

Scientific Work and Program—V. A. Muller, Reno; J. C. Ferrell, Fallon; A. Huffaker, Carson City.

Necrology—Mary H. Fulstone, Smith; Donald Maclean, Reno.

Council—S. K. Morrison, Reno; A. L. Stadtherr, Reno; Hal L. Hewetson, Las Vegas; P. D. McLeod, Tonopah; J. T. Reese, Yerington; William Brennen, Eureka; William Howell, Gardnerville; Charles E. Sweezy, Winnemucca; F. M. West, Lovelock; M. J. Rand, Ely; William Riley, Gold Hill.

Entertainment—C. E. Secor, Elko; W. A. Shaw, Elko; J. R. Eby, Elko.

Public Health and Education—Henry Albert, Reno; W. A. Shaw, Elko; M. R. Walker, Reno.

Military Affairs—The president, vice-president, and secretary.

California Board of Medical Examiners

(Reported by C. B. Pinkham, Secretary)

The judgment of the Federal Court in Sacramento, which some months ago sentenced Stuart N. Coleman, M. D., to five years of hard labor in the federal penitentiary, following his conviction of a violation of the narcotic law, was upheld by the United States Circuit Court of Appeals, and as a result Dr. Coleman must serve the sentence imposed. A hearing has already been held before the Board of Medical Examiners to show cause why his license to practice in California should not be revoked, and final disposition will be effected at the February, 1925, meeting.

Gertrude Steele, licensed in California by the 1909 Act as a naturopath, reported fugitive on a Los Angeles manslaughter charge, which is alleged to have arisen following the death of one of her "beauty patients," has been served with a citation by publication, calling her before the Board of Medical Examiners at the February, 1925, meeting to show cause why her license to practice in California should not be revoked. According to recent information, she has been located in Oberhausen, Germany. The records of the board show that other deaths are alleged to have followed her "beauty treatments." Not long since, a Los Angeles Superior Court was reported to have handed down a judgment for \$2500 damages, and at about the time of Gertrude Steele's sudden departure for parts unknown a suit for damages for \$50,000 was reported filed in the Los Angeles courts, each as the result of her so-called "beauty treatment."

Leon Hurwitz, licensed to practice in this state several years ago on diploma, reported confined in the federal penitentiary, Leavenworth, Kan., November 1, 1924, under sentence of three years, has been served with a citation to show cause why his license should not be revoked at the February meeting, based on his conviction of violation of the Harrison Narcotic Act.

James W. Richards, who recently plead guilty in the Federal Court of San Francisco to a charge of violation of the Harrison Narcotic Act, and sentenced to two years' imprisonment in the federal penitentiary at Leavenworth, Kan., has been cited to show cause why his license should not be revoked at the February meeting based on his record of conviction. Dr. Richards is alleged to have forged the name of a San Francisco physician to a prescription for narcotics.

A complaint has been filed with the board, charging Joseph Sanford, D. C., licensed as a drugless practitioner, with violation of Section 14 of the Medical Practice Act, the complaint having been filed by George D. Gillespie, D. C., Clarence G. Burt, D. C., and Harry C. Bond, D. C., alleging that Dr. Sanford made misstatements in connection with his application for a drugless practitioner license to practice in California.

James Warburton, M. D., has been called before the board in connection with the diploma mill conspiracy cases.

Robert W. Renwick, M. D., alleged to have protected an unlicensed chiropodist named Roy Finney, who, operating a chiropody stand on Main street, Los Angeles, is asserted to have so thoroughly "baked" the feet of a patient that gangrene resulted and the patient later died. It is reported that, about a year ago, Roy Finney was sentenced in Department 2 of the Los Angeles Police Court to pay a fine of \$200 or serve 180 days in the city jail. Appeal pending before Superior Court Judge Carlos Hardy of Los Angeles.

The following physicians and surgeons have been called before the board at the February, 1925, meeting to show cause why their licenses should not be revoked on complaints alleging narcotic violation: James T. Fisher, M. D.; James J. Martin, M. D.; and Newton J. Rice, M. D.

Charles R. Knox, M. D., and Peter McGrath, M. D.,

have been cited on complaints, charging violations of Section 14 of the Medical Practice Act.

Unlawful use of the prefix "Dr." resulted in a fine of \$100 recently imposed on Jules Marton, following his plea of guilty in a Los Angeles court.

Petition for the release of Dr. Ephriam Northcott from San Quentin prison, on a writ of habeas corpus, has been denied.

The extradition of Dr. J. W. Peacock to the state of Georgia, granted by Governor Richardson some time since, was nullified by the Superior Court of San Diego, which ruled in favor of the physician on a writ of habeas corpus, thus denying Georgia extradition.

Public records and other matters in the office of any public officer are at all times during office hours open to any citizen of the state, according to newspaper reports of a recent opinion of Attorney-General U. S. Webb.

"Dr." J. Oscar Francis Haas, who is reported to have been sentenced to serve two years in San Quentin for obtaining money under false pretenses, and in 1919 to having been arrested in San Diego under the name of "Rev. J. O. Francis Haas, divine healer," accused of charging one of his patients \$4800 for treatments, recently plead guilty in Los Angeles to a violation of the Medical Practice Act. He was reported to be in possession of a diploma from the St. Louis College of Physicians and Surgeons, but the secretary of the college reports no record of Haas.

Too Many Rats—"There are as many rats in this country as there are people, and the total yearly damage they cause amounts to \$200,000,000. It would take the labor of 200,000 men to produce the material eaten and destroyed by these rats. It would require about 5,000,000 acres to produce the grain they destroy. They are also the perpetrators of plague."—Dearborn Independent.

Medicine Before the Bench

Findings and Comments of the Courts on Acts and Omissions of Doctors

[EDITOR'S NOTE—*The law reports contain many interesting decisions, involving the reputations and fortunes of doctors. In this column in each issue a brief summary of one or more decisions and comments of the several courts of last resort upon the cases will appear. The matter will be selected by our general counsel, Hartley F. Peart, who, with Mr. Hubert T. Morrow, attorney for Southern California, will contribute from time to time.*]

The liability of a physician for the performance of an unauthorized operation upon a patient was involved in a decision wherein the Supreme Court refused to reverse the judgment and verdict of the jury in favor of the plaintiff and against the physician for \$14,332.50. It appeared from the evidence that plaintiff consulted her physician with reference to a perforation in the lower portion of the drum membrane in her right ear, and a large polyp in the middle ear. An operation was advised and plaintiff consented to this operation and was placed under an anesthetic for that purpose. After the plaintiff was anesthetized the defendant made a thorough examination of her left ear and found it in a more serious condition than her right one. The physician then decided to operate upon the left ear instead of the right, the operation being successfully and skillfully performed. Plaintiff claimed that the operation greatly impaired her hearing, seriously injured her person, and, not having been consented to by her, was wrongful and unlawful, constituting an assault and battery.

Upon appeal, in refusing to reverse the verdict of the jury against the doctor, the court quoted, with approval, the language of a former decision, wherein a physician was held to have wrongfully removed the ovaries of a patient, saying:

"Under a free government, at least, the free citizen's first and greatest right, which underlies all others—the right to the inviolability of his person; in other words, the right to himself—is the subject of universal acquiescence, and this right necessarily forbids a physician or surgeon, however skillful or eminent, who has been asked to examine, diagnose, advise, and prescribe (which are at least necessary first steps in treatment and care), to violate, without permission, the bodily integrity of his patient by a major or capital operation, placing him under an anesthetic for that purpose and operating upon him without his consent or knowledge. . . . The patient must be the final arbiter as to whether he will take his chances with the operation, or take his chances of living without it. Such is the natural right of the individual, which the law recognizes as a legal one. Consent, therefore, of an individual, must be either expressly or impliedly given before a surgeon may have the right to operate." There is logic in the principle thus stated, for, in all other trades, professions, or occupations, contracts are entered into by the mutual agreement of the interested parties, and are required to be performed in accordance with their letter and spirit. No reason occurs to us why the same rule should not apply between physician and patient. If the physician advises his patient to submit to a particular operation, and the patient weighs the dangers and risks incident to its performance, and finally consents, he thereby, in effect, enters into a contract authorizing his physician to operate to the extent of the consent given, but no further. . . . The medical profession has made signal progress in solving the problems of health and disease, and they may justly point with pride to the advancements made in supplementing nature and correcting deformities, and relieving pain and suffering. . . . The methods of treatment are committed almost exclusively to the judgment of the physician, but we are aware of no rule or principle of law which would extend to him free license respecting surgical operations. . . ."

The Gorgas Memorial—Medical editors have been asked by the executive committee of the Gorgas Memorial to publish a lengthy appeal for support of the movement. In addition to what has already been repeatedly published, the document states that, "inasmuch as the Gorgas Memorial is primarily a medical movement, it must have the united support of the profession if it is to make the proper impression on the general public."

The directors announce the very praiseworthy idea to make of the General William Crawford Gorgas Memorial "not one of marble or bronze," but a permanent living organization in the form of a great health foundation typical of his work in "research and curative medicine."

We presume that Gorgas' really great work in preventive medicine was accidentally omitted from the publication.

"If the medical profession is to maintain the high standing to which centuries of labor in behalf of suffering mankind entitles it, it is essential that a definite organized effort be made to familiarize the public with such facts as will impress upon it the importance of medicine's contributions to human welfare.

"One of the objects of the Gorgas Memorial is to furnish a channel through which 'better health' information may be disseminated. This, says the committee, "cannot be done by individual physicians. It must be conducted by a dignified, ethical organization, controlled by the medical profession. The name of Gorgas is synonymous with 'better health.' No more appropriate name could be adopted for a movement that has for its object the development of co-operation between the public and scientific medicine for the purpose of improving health conditions by implanting the idea in the mind of every individual that scientific medicine is the real authority in all health matters, and as such should be recognized as the source of health instruction."

California physicians will appreciate such an indorsement of both an idea and a name under which they have conducted for years a magazine (Better Health); a syndicated newspaper service (Better Health Service) and have for longer years conducted a better health crusade for every citizen we could reach.

Our physicians will feel that it is rather late for any organization to be talking of "adopting" the name Better Health, already well established and protected by priority, usage and law.

"Every doctor is requested by the governing board to take a personal interest in the Gorgas program and to see that his community is adequately represented on the state governing committee. Those invited to serve as founder members of the state governing committees are requested, as they accept membership on the committee, to subscribe \$100 to the Endowment Fund, payable within two years."

The organization is controlled by a large board made up of physicians, government officials, and laymen. Doctor Franklin Martin of Chicago is chairman of the board and Doctor Ray Lyman Wilbur of California appears to be the one representative of Western America.

"Many persons think that education is something that we may give a child," says Angelo Patri (Liberty). "No power on earth can do that. Education is something that a child must take. He takes it up from the earth and transforms it into intelligence by the experiences that he gathers through his nerves and muscles—and his hands."

"We have one United States Senator who believes Mrs. Eddy was a deity," says J. E. Dildy (Texas Medical Journal). "The banker carries an Irish potato for rheumatism; the congressman signs the Tanlax ad., while the legislator votes for the chro and "totes" buckeyes for piles."

"The doctors of a community can tell the people what to do in order to prevent disease, but they are powerless to enforce their advice," says the Long Island Medical Journal.

Medical Economics and Public Health

Medical Society Dues—At the recent meeting of state medical association secretaries held in Chicago it developed that some states have medical society dues of as much as \$25 per year, and there are a number of states that have dues of \$15 per year. The general opinion from these states was that doctors do not object to dues if they really are getting something for the money expended, and in the states where the dues are \$25 per year many of the doctors have said: "Raise the dues to \$50 per year if you can do any more than you are doing now." . . . "Isn't it ridiculous for doctors to offer complaint concerning the insignificant sum asked for medical society dues for an entire year when the average doctor will spend more than that amount in one night for entertainment at the theater, and does not bat an eye to pay ten times as much as a penalty for frivolity of one kind or another."

Everyone Practices Public Health—Every citizen has his effect on the comfort, health and safety of others, and so he practices public health. Every voter practices public health when he supports or opposes the budget of the health department. Every mother practices public health when she either isolates her child who has a cold, or conceals the sickness while she makes her own diagnosis and takes the child to the movies in order to amuse it.—Frank Overton, in *Health Quarterly*, New York.

Thus Did Athens and Rome Fall—"Today we are spending on our asylums, hospitals and jails more money on the various grades of mentally subnormal children and adults, imbeciles, morons, and border-line cases, than on those of normal mentality."—The Canadian Medical Association Journal.

Does Loose Prescribing Mean Loose Thinking?—"The patient is often told to 'eat a simple diet and take care of his general hygiene,' and then he is hurried out," insists G. H. B. (The Commonwealth). "This often does not mean any more to the doctor than it does to the patient. It is surprising how varied is the layman's interpretation of the modern slogan 'green vegetables.' Some feel that it includes potatoes, rice, and even macaroni. 'Regular exercise, preferably out of doors,' may be as freely recommended to the steeple jack as to the stenographer, and probably means no more to the one than to the other. A classic example of the impossible is for the woman with seven children to 'go home and keep off her feet.'"

"Again," says the author, "how little foundation in known fact is there for much that is advised. What should we say as to the consumption of water in the obese? How about the hoary prejudice against water with meals, lest the saliva and gastric juice be diluted? Is it not better to drink at meals than not to drink at all? In one place it happened that one examiner was giving almost the identical diet to the overweights that another was giving to the underweights, and in not a few points it was impossible to decide which was right. Many sins are committed in the name of constipation from the cannon ball to the cold prune floating in the glass of water before breakfast. Just what is 'roughage' and may its use not be abused? What is the normal bowel rhythm, once in eight or forty-eight hours, or is there really any such rhythm? Is it better to pound the pavement in the fresh air or exercise in a gymnasium? Just why is hot food better than cold? How much sleep is 'more sleep'? One might go on indefinitely. But in the presence of the health examination, does it not behoove us all to take down and thoroughly inspect and dust and even selectively discard our old store of hygienic generalities?"

Are We Converting Industrial Accident Laws into Compulsory Health Insurance for Everybody?—There seems to be a spirit of active competition between the Industrial Accident Commissions of several states as to which can excel in spreading the provisions of the laws over the largest and most complete set of diseases. Addi-

tions of new diseases to the compensable list are occurring very rapidly, and at the present rate nearly all diseases will be compensable within a few years.

"Riveters' osteomyelitis," said to be an "industrial cousin" to painters' colic, was recently added to the list in California.

Newer Ideas in Health Service—One must read widely and extensively these days to keep up with the innovations designed to extend health service to humanity.

Some of these influences and ideas seem sound and are calculated to improve health service and at the same time make it more economical. Others are but indifferent gestures and some are obviously calculated to serve the promoters rather than the public.

One of the newer and apparently promising ideas is being crystallized into what is called "The Physicians and Surgeons' Institution of Chicago." A group of 200 well-known physicians and specialists have organized themselves into a diagnostic service to be operated in connection with a good hotel. Patients will reside in their hotel during the period of study unless and except for a brief period, when they may occupy space in the "Institution" for special study.

The institution "will provide for accurate and complete diagnosis through the finest obtainable equipment and physical plant. The working organization includes a staff of full-time men, and a consulting staff of specialists of recognized ability."

"*This institution is not going to treat any one,*" says the Illinois Medical Journal. "It will be merely as perfect as possible a piece of mechanism available for any physician, irrespective of location, to use in achieving the best possible results for his patients, *without having* the patient leave the *control* of his own physician. This institution will be the public servant of every qualified, honest doctor, as well as of the public, and will be pledged to the most efficient assistance in the most economical manner."

"Larger hospitals will be benefited from this new organization through referred cases. Smaller hospitals will gain appreciably because, lacking an expert laboratory staff of their own, that of this institution, will be in readiness to aid diagnosis."

"Physicians at any point in the United States will find help here. The scope of this institution will be widespread, as any doctor anywhere may refer for diagnosis any of his difficult cases secure in the knowledge that the cases will not be retained, but the case and the diagnosis will be returned to this doctor, and the treatment he sees fit to give will be a matter between himself and his professional conscience."

Sound Investments—Under this title, the Anglo-London-Paris Company, advertisers in CALIFORNIA AND WESTERN MEDICINE, have issued an attractive little booklet for persons who wish to secure quickly concise descriptions of many western, municipal, irrigation and corporation bonds.

Committee of Massachusetts Legislature Recommends Shortening Nursing Education—A committee of the Massachusetts legislature, after studying the whole question of education and licensure of those engaged in serving health, has recommended that the legal requirement for nursing education be reduced to two years and that no legal standing be given to either chiropractors or midwives.

The List of Compensable Diseases Still Expanding—The latest addition to the list is *infected mosquito bites*. The beneficiary, under the recent decision, was a mouth-breather. While asleep, he was bitten on the tongue by a mosquito and the wound became infected.

Step by step we are bringing more and more diseases into the compensable class under the Workmen's Compensation Act. The rulings of the Commission are all that delays more or less complete state medicine in California under the screen of an industrial accident law.

Are You Educating Your Patients in Health?—Almost everyone is busy "educating" everyone else about how to keep well and how to treat disease. Doctors know that fully 75 per cent of this "education," whether pre-

sented by spoken or written word, is unreliable, inapplicable, dangerous or mischievous. Increasing numbers of other intelligent people are rapidly approaching the same inevitable conclusion. We are destined to see the end of the "fad" within a few years, after which physicians and nurses will again have more to say to their patients individually about health as a peculiarly personal matter requiring personal service and publications supervised by medical men will largely occupy the field of general health advice. The time is about right for physicians to take advantage of the situation by more energetically and intelligently carrying forward a system of health instruction for their own patients than has been the custom.

As Doctor Le Grand Kerr (Medical Economics) so well says: "Your patients want health instruction; they seek it from you first of all, but failing in that will seek it elsewhere."

"Very often the patient needs particular instruction, which he or she does not seek until some suggestion is made."

Dr. Le Grand Kerr has—and so have many other doctors—printed instruction blanks, interlined for additions and modifications to meet the needs of individual patients. On these charts, in addition to general instructions, are printed a number of captions, of which the following are examples:

1. A normal, healthy childhood is the best life insurance any adult can acquire.
2. The certain thing about health is its uncertainty; guard it.
3. Do not let your good intention suffer by inattention.
4. The malnourished child may make the pessimistic adult.
5. "They say" harms more children than it helps.
6. Children do not outgrow disease; they must be helped.
7. Teething is a natural process; it may cause discomfort; never disease.
8. What helps a neighbor's child may harm yours.
9. Diet is often more important than medicine.
10. No two babies are alike; then, why not treat them as individuals.

The Pinellas County (Florida) Medical Society of St. Petersburg, Fla., carried the following advertisement in the daily papers:

"The following physicians are members in good standing of the Pinellas County Medical Society, the Florida State Medical Association, and the American Medical Association": Under this advertisement were signed the names of thirty-six doctors with their office addresses. The object of this advertisement was to counteract the influence and prestige which was being gained by certain advertising doctors, some of whom were as blatant and as unscrupulous as any that can be found in the daily press of the nation.

After seven months of this advertising—"The members of the society feel gratified with the results attained. Not only have they counteracted the prestige which they seemed to be losing, but they fixed the ethic standards of the profession clear and strong in the public mind. At the same time they established themselves individually as being physicians of the first rank, and worthy of the respect and confidence of their fellow-physicians."—Medical Economics.

The Public Services—Examinations of candidates for entrance into the United States Public Health Service will be held at San Francisco, Cal., March 2, 1925.

Candidates must be not less than 23 nor more than 32 years of age, and they must have been graduated in medicine at some reputable medical college, and have had one year's hospital experience or two years' professional practice. They must pass satisfactorily, oral, written and clinical tests before a board of medical officers and undergo a physical examination.

Successful candidates will be recommended for appointment by the President with the advice and consent of the Senate. Requests for information or permission to take this examination should be addressed to the Surgeon-General, United States Public Health Service, Washington, D. C.

Poor Chiropractors—The chiropractors apparently made their initiative law so exclusive that they cannot get themselves in under its provisions. One board of examiners appointed by the Governor under the provisions of the law has been ousted by the Supreme Court. Charges similar to those used in the first instance have been preferred against the second board. In the meantime an injunction was obtained preventing the board from issuing licenses. By some sort of understanding or misunderstanding, the board issued some 400 licenses and now there is other and more litigation. Chiropractors did not bother much about the law governing practice before, and the fact that they cannot qualify under their own law is not interfering with "business," if signs and advertisements mean anything.

When a horseman is examining a horse, he always pulls out the animal's tongue and looks at his teeth. This is for the purpose of ascertaining his age and whether or not his grinders are in good condition. . . . Many years of experience have taught our physicians that if a patient shows the results of considerable good dental work, he will as a rule pay his physician's fees. Moral: Look in your patient's mouth, not only in the interest of his health, but before you determine upon his credit.—Medical Economics.

Tell "Our Story" to the Public—"The question still remains as to how we are to gain the sympathetic understanding and energetic co-operation of the public. "Without this," believes Gordon S. Fahrni, M.D. (The Canadian Medical Association Journal), "we cannot make progress. Business and other forms of lay organizations, as well as the individuals, are waiting to be informed on the big questions of preventive medicine and of the care of the sick. Many of them have brightening mental pictures of the situation, seeing as they do the abuse of public money in the present system of administration of our charities and public health institutions. They are groping about in the dark, wondering where to begin. I consider it is the duty of the medical profession to show the way in this big question, and by so doing gain a more sympathetic understanding from the public."

Mrs. Wallace Reid Foundation—Some of our members are making inquiry about the Mrs. Wallace Reid Foundation of Los Angeles.

A recent circular letter upon the stationery of that organization shows "Dr. Nathan O. Reynolds, A. M., M. D., as medical director and Harry M. Owens, personal business representative." This letter is addressed to a physician and contains the following statements:

"Our treatment for drug addiction is now being successfully administered with little, if any inconvenience to the patient and a *complete elimination of the drug, with restitution of the patient to a very healthy and cheerful condition within two weeks.* Physicians and discharged patients are now endorsing the treatment in highest terms.

"Our plans of operation are semi-philanthropic and in consequence our charges, considering the *wonderful results attained*, are quite reasonable."

Records of the Board of Medical Examiners show:

"Dr. Reynolds is a graduate of Creighton Medical College, April 27, 1912, and the holder of California physician's and surgeon's reciprocity certificate No. C-1149, issued April 8, 1919, based upon Nebraska license issued June 12, 1912, after a regular written examination."

We would like very much to have the names and addresses of physicians who "are now endorsing the treatment in the highest terms."

All physicians would also be highly appreciative of conclusive evidence of the "wonderful results" being secured at this "Foundation."

For the information of inquiring members of the California Medical Association, it may be stated that, so far as we can find out, the "Mrs. Wallace Reid Foundation" has not been approved, accredited, or endorsed by any medical organization.

Should Fees Be a Personal Matter?—"The Louisiana Medical Society has never adopted a schedule of fees such as other medical societies in many sections of the

country have done," says the New Orleans Medical and Surgical Journal.

"Fees for house calls, as a rule, should be in excess of office charges. Night calls more than day visits. Distance to be traveled, length of time spent at the bedside, character of service rendered, and the type of patient treated, and the patient's economic condition should all be included in determining the charge.

"A flexible scale, excepting routine work, will meet all conditions, assuring to the patient the fullest and fairest treatment, and to the doctor a competence commensurate with his time, service and skill. *Medical fees should not be standardized, and popular impression to the contrary should be corrected.*"

Business Methods in Charity—Eastern newspapers are prominently featuring the Charity Services of Doctors, as expressed in money values. Calculated upon a basis of \$1 a visit, the services of doctors run into millions of dollars, even for a single group associated with a single hospital. If figured upon the basis of \$1 a visit; \$1 for laboratory examinations; and \$5 for x-ray, and even \$10 for operations, the services for which no compensation is asked or received for the citizens of California during 1924 would be in excess of \$10,000,000. It would exceed \$4,000,000 in San Francisco alone.

If we are going to set up our charity work in dollars and cents, why not be generous enough to include the figures for medical service, as is done for every other kind?

How many colds do you have in a year? The average for Americans is four apiece. It takes about three weeks to recover from a cold. So, then, most people are wretched and ineffective a fourth of their time as a result of this common ailment. A stamping out of colds would be more valuable to the world than the discovery of an elixir which would add a decade to life.

More Should Do So—"Personally," says a layman (Medical Economics), "I am through with taking advice that doesn't fit me, even if it comes by radio from high medical authorities. Twice a year now I have myself thoroughly examined and surveyed by my physician, and if there is any trouble indicated, I have it attended to at once. I keep the bridge running away from me; I do not worry about crossing it. The periodic health examination is good sense and good business. I am just as much for it as I am for regular inspection of elevators and of steamboats and factory boilers. Then, if anything is found wrong, I am convinced that an expert ought to hunt the trouble and remove its cause."

Discovery Always an Evolutionary Process—"No discovery in the basic medical sciences, no advancement in the art of healing is to be credited to any single individual," says C. M. Jackson of the National Research Council. "Even the greatest heroes of medicine, those most richly endowed with the precious gift of creative imagination, are indebted to their predecessors for instruction and inspiration, to their contemporaries for criticism, and to their successors for the final adaption and evaluation of their most original products."

"Full service to the patient calls for team work. The captain is the doctor. No team is any more worth while than its constituent members. The nurse, the social worker, the laboratory expert, the specialist, the pharmacist, the physiotherapist, and others may one or all constitute the team which the physician directs."—Medical Economics.

Medical License as Old as Medicine—In India, 600 years B. C., a student, after completing a rather hard course of study, had to petition the king and secure his permission before he could practice medicine.

After 3000 years of "progress" a fad may be substituted for a hard course of study; advertising for a petition to the king and membership in a fighting organization in lieu of permission from the government.

The Michigan State Medical Society at its last annual meeting amended its constitution and by-laws to fix the annual membership dues at \$10. This was done to

extend its work and increase its usefulness. Thus the Michigan State Medical Society has again recorded itself as an organization that refuses to stand still or even to move slowly in discharging its recognized duties to its members and its state.—A. M. A. Bulletin.

Several other medical societies are expanding their constructive programs and taxing themselves to pay for the increased service.

The Board of Education is operating a "Guidance Clinic" in Minneapolis. They are also operating a hospital as a "School for Tuberculous Children." A few doctors of medicine are on their large staffs largely as "advisors" and "consultants."

Pharmacy Advertising—Good reliable pharmacy supplies are as important to the doctor and his patient as is reliability in surgical instruments or any other equipment or service. CALIFORNIA AND WESTERN MEDICINE takes pleasure in calling attention to our growing list of advertisers of pharmacy supplies and prescription pharmacists whose products and service may be depended upon. These pharmacists are patronizing, and thereby helping to support the publication owned and published by physicians. They are entitled to your consideration. They are, Broemmel's Prescription Pharmacy, Fitzhugh building; Butler's Pharmacy, Flood building; Exclusive Prescription Pharmacies, with five stores in San Francisco and one in Oakland; H. L. Ladd, 343 Powell street; Lengfeld's, 216 Stockton street, and F. J. A. O'Ferrall, The Dispensary, 5199 Geary street.

All of these pharmacies are in the bay district, but we hope to carry, in early issues, the announcement of reliable pharmacies in Los Angeles and other cities of the state for the convenience of our many members there.

California Pollens—Through an error, the advertisement of California pollens, M. L. Austin, 3201 Fifth avenue, Sacramento, was omitted from the January issue of CALIFORNIA AND WESTERN MEDICINE, although it has been running continuously for the last two years. For this we wish to apologize. The production and use of reliable pollens is a business of growing importance, less seasonal in California, of course, than in many other places.

Transportation of the sick is an important and growing movement among many agencies that serve health. Like other services, to be of the best, it must be conducted by those experienced in the work. We are glad to note that the American Ambulance Company of San Francisco announces itself in this class in the advertising pages of CALIFORNIA AND WESTERN MEDICINE every month.

E. R. Squibb & Sons—We are particularly glad to welcome to our advertising pages again the well-known house of E. R. Squibb & Sons. This contract for a page space ought to reassure those physicians who had grown curious about whether this firm had decided to make its appeal in California exclusively to the consumer instead of inviting the endorsement of physicians as had been their previous custom.

Infant Foods—It is always difficult to know just what infant foods to accept and what to reject in the advertising columns of an ethical medical journal. Many of these products are worth while; many are purely commercial, while others have both advocates and critics. We feel, however, that CALIFORNIA AND WESTERN MEDICINE is making no mistake in accepting, and thereby endorsing, the copy of the Nestle's Food Company and of the Merrell-Soule Company, manufacturers of Klim, which appear for the first time in this issue. In addition, you will find the announcements of our old friends, Denos Food Company; Horlick's Malted Milk; Knox Gelatine; Mead Johnson & Company; Mellin's Food; and SMA of the Laboratory Products Company.

One Group of Specialists Appeal to Another Group—The Wells Fargo Bank and Union Trust Company, who are advertisers in CALIFORNIA AND WESTERN MEDICINE, have issued to all physicians an attractive and unique pamphlet under the title of "There Aren't Enough Hours in the Day."

Clinical Notes, Suggestions and New Instruments

TONSIL LIGATING INSTRUMENTS

This set of instruments, devised and improved by Doctor C. R. Bricca of San Francisco, consists of two forceps and mouth gag (Davis). The forceps, as illustrated, are an angle-bent haemostat, which carries a looped ligature with a single knot, so that when any vessel is seized the ligature encircling the vessel enables the operator to tie the same, visibly, by aid of the forceps with a ring on the upper blade. One end of the ligature is passed

through the ring, and by pushing the knot over the end of the haemostat and with gentle traction on the other strand the knot is easily completed.

These instruments eliminate the use of all needles and traumatizing haemostats, and also the tying of the pillars together. The instruments being angle-bent, allow the operator an unobstructed view of the surgical field, and the hands of the operator are outside the visual line. Any size blood vessel can be visibly ligated with these instruments, regardless of location.

These instruments are manufactured and distributed by the Travers Surgical Company, San Francisco.

PERFORATIONS OF STOMACH AND DUODENUM DUE TO ULCERS

Comment by Ralph Van Vranken, M. D.,
Los Angeles, Calif.

There is probably no surgical condition that has been more often discussed or results that have been more often fatal than perforations of the gastro-intestinal tract. Early diagnosis followed by immediate surgery is, without doubt, the most adequate method to lower the mortality.

In all perforations of the gastro-intestinal tract it is of the greatest importance that the site of the perforation be determined prior to surgical interference. Too often an incision is made in the lower abdomen, expecting to find an appendix as the seat of the trouble when in reality the stomach is the focus of the condition. The increased hauling around of the viscera and contamination due to such an error is often most telling on the patient, say nothing of the embarrassment to the occasional individual that operates for an acute appendix,

sends patient back to bed, and in the morning, when the autopsy is done, the pathologist finds a perforation of the stomach.

It is with this in mind that I wish to bring out a few cardinal points that help to differentiate this condition from other acute conditions of the abdomen. The following points I have observed from about six or seven perforated cases that I have seen in the last few years.

The patients were usually about middle age. All the cases that I have seen have been men. The patients were thin, emaciated, and in a condition of severe shock. They usually gave a history of previous stomach trouble of possibly years' duration. Soda bicarbonate had previously given relief. The present trouble struck them suddenly like a knife going through them. The cases were all pictures of acute peritonitis and, if seen early, the pain was more noticeable on palpation at the pit of the stomach or over the area of the perforation. The usual case was sweating when seen, or had sweated rather profusely before. Quite frequently there was pain in the right shoulder. One case seen, this was the main complaint of the patient. Hiccough, vomiting, and markedly rapid respiration was noticeable separately or in combination in about one-half of the cases.

The temperature was usually close to normal or slightly subnormal. The pulse was rapid and thready. The blood pressure showed a decrease. It is of significance that the blood picture shows little variance from normal, save there being a slight decrease in R. B. C. and hemoglobin. The urine often showed a trace of albumin and acetone.

These cases were operated on by an incision above the navel, in the mid-line. The sight of the perforation was readily accessible in all cases, except one which was in the posterior part of the duodenum. The holes were purse-stringed and then lapped over, drains inserted under the liver, another one in the midregion, and a third drain was brought up through a stab wound just above the bladder.

Patients were put to bed in Fowler position and given nothing by mouth for three days except a mouth wash,

which was given the patient from the start. Normal saline was given under the skin, about 1000 cc. every eight hours, and drop method by rectum continuously until the third day, when Sippy treatment was started.

Five patients left the hospital alive and one died. This one was operated on about twenty-four hours after rupture, the others from six to eighteen.

As a summary, I might say that patients with perforations of the stomach or duodenum should be operated on as soon as a diagnosis is made. It is very hard to differentiate between perforations of stomach and duodenum. The abdomen should be opened above the umbilicus, so as to avoid undue handling and contamination. Cases of acute peritonitis that give a history of acute onset where pain is or was greatest in the abdomen above the umbilicus, where there is hiccough, pain in the shoulder or rapid respiration, where the temperature is practically normal, and the blood picture shows little variance from normal are usually perforated stomachs or duodenal ulcers and should be treated as such.

1039 East Vernon Avenue.

Medicine being a science of man, for man, and by man, must be learned from man through a study of man to a large though varying degree. The evil that holds modern medical education in its grip is too much theory and not enough practice; too much talk about the bedside and not enough sitting by it.—*Illinois Medical Journal*.

A great physician long ago said that a scientist who could not make any scientific fact clear to any intelligent person did not know his fact or it was not a fact.

TRUTH ABOUT MEDICINES

New and Non-official Remedies

(Abstracts from reports of Council on Pharmacy and Chemistry, A. M. A.)

Note—These do not represent all of the actions of the Council, but they do represent those remedies manufactured by firms who co-operate with CALIFORNIA AND WESTERN MEDICINE in its advertising columns, and thereby with the physicians of California.

Iletin (Insulin—Lilly) U-80—Five cc. ampules containing 80 units of iletin (insulin—Lilly) (New and Non-official Remedies, 1924, p. 152) in each cc. Eli Lilly & Co., Indianapolis.

Ampules Adrenalin Chloride Solution Rx 1, 1:1000, 1 cc.—A solution of adrenalin chloride. Parke, Davis & Co., Detroit.

Ampules Adrenalin Chloride Solution Rx, 1:2,600, 1 cc.—New and Non-official Remedies, 1924, p. 117. Parke, Davis & Co., Detroit.

Ampules Adrenalin Chloride Solution 1:1,000, 1 cc. New and Non-official Remedies, 1924, p. 117. Parke, Davis & Co., Detroit.

Thigenol—Solution Sodium Sulpho-Oleate (Roche)—A solution of the sodium salts of synthetic sulpho-oleic acid containing 2.85 per cent of sulphur. Thigenol has the actions and uses of sulphoichthyolate preparations (New and Non-official Remedies, 1924, p. 350). The Hoffman-LaRoche Chemical Works, New York.

Hypodermic Tablets Strophanthin 1/100 grain (Lilly)—Each tablet contains strophanthin U. S. P. 1/100 grain. Eli Lilly & Co., Indianapolis.

Hypodermic Tablets Strophanthin 1/120 grain—Lilly.—Eli Lilly & Co., Indianapolis.

Ampules Ouabain 0.0003 gm. (1/128 grain)—Lilly—Each ampule contains ouabain crystallized—N. N. R., 0.0005 gm. in 2 cc. of a buffered, sterile normal salt solution. Eli Lilly & Co., Indianapolis.

Antidysenteric Serum—P. D. & Co.—(New and Non-official Remedies, 1924, p. 301.)—An antidysenteric serum, also marketed in packages of one syringe containing 20 cc. Parke, Davis & Co., Detroit.

Insulin (Squibb)—A brand of insulin (New and Non-official Remedies, 1924, p. 149). It is supplied as insulin (Squibb) 10 units (5 cc. vials containing 10 units in each cc.), and insulin (Squibb) 20 units (5 cc. vials containing 20 units in each cc.). E. R. Squibb & Sons, New York.—*Journal A. M. A.*, November 8, 1924, p. 1509.

Pituitary Extract—Lilly (Obstetrical)—A slightly acid aqueous solution containing the water soluble principle or principles of the fresh posterior lobe of the pituitary body of cattle. It is tested for oxytocic action on the isolated uterus of the virgin guinea pig against a standard solution prepared from defatted desiccated posterior lobe powder and adjusted so that its strength is equal to that of a 5 per cent solution of the fresh posterior lobe of the pituitary gland. For a discussion of the actions and uses, see general article, Pituitary Gland, New and Non-official Remedies, 1924, p. 225. Pituitary extract—Lilly (obstetrical) is marketed in ampules containing 0.5 cc. and 1 cc., respectively. Eli Lilly & Co., Indianapolis.

Pituitary Extract—Lilly (Surgical)—A slightly acid aqueous solution containing the water soluble principle or principles of the fresh posterior lobe of the pituitary body of cattle. It is tested for its pressor action on the blood pressure of mammals and for oxytocic action on the isolated uterus of the virgin guinea pig against a standard solution prepared from defatted, desiccated posterior lobe powder and adjusted so that its strength is equivalent to that of a 10 per cent solution of the fresh posterior portion of the pituitary gland. For a discussion of the actions and uses, see general article, Pituitary Gland, New and Non-official Remedies, 1924, p. 225. Pituitary extract—Lilly (surgical) is marketed in ampules containing 1 cc. Eli Lilly and Co., Indianapolis.

Secacornin—Ergotin (Roche)—A solution of the ac-

tive principles of ergot in a menstruum consisting of distilled water, glycerin and 7.5 per cent of alcohol. One cubic centimeter secacornin corresponds to 4 gm. ergot, U. S. P. The actions and uses of secacornin are the same as those of ergot. It may be given by intramuscular injection. Hoffmann-LaRoche Chemical Works, New York.—*Journal A. M. A.*, November 29, 1924, p. 1769.

Harmonizing Workmen's Compensation Laws—The National Industrial Conference Board, Inc., makes the following suggestions for increasing the efficiency of industrial accident laws:

"At least one member of each state compensation board should be a physician who should also be the medical director of the board.

Each board should have a consulting staff of specialists to advise it on medical problems.

Examining physicians should be appointed by the state board on recommendation of the consulting staff on the basis of their professional qualifications.

Only licensed graduates of recognized medical schools should be permitted to treat compensations cases.

Medical fees should conform to the average charges for like work in the community.

'Medical treatment' should include all necessary medical, surgical, and hospital care and attendance and also such supplies and appliances as may be necessary.

Examination of an injured worker should be made immediately following the injury, and later examinations should be at the expense of the party requesting the same.

The choice of physician should be made by the employer or be made by the employe from a list of local physicians compiled by the employer.

Copies of the findings of examining physicians should be furnished to all interested parties, and reports and testimony of other physicians should not be allowed before the board till medical representatives of the other party have knowledge of the information to be given.

The refusal of medical treatment by the injured worker should release the employer from further responsibility in the matter.

Amputations should be made with regard to the function of the part remaining and not alone with regard to the amount of tissue removed, which latter proceeding might leave a tender appendage, useless for applying an artificial member and would, at the same time, in some states reduce the compensation of the injured employe.

Autopsies should be made at the request of the employer, the beneficiaries, or the state board, and should be paid for by the party requesting them.

Compensation for disease alleged to be due to accident should be granted only on proof of direct causal connection between the accident and the onset of the disease.

Compensation for the aggravation of latent or pre-existing disease should be limited to the degree of disability caused by the aggravation.

The per cent of reduction of vision and its economic valuation should be based on the age and occupation of the employe, and each case should be judged on its merits and not by a predetermined schedule.

Claims that hernia has been caused by employment must be made within twenty-four hours of its alleged occurrence and must be supported by proof of certain specified conditions.

Compensation should be granted for occupational diseases that are peculiar to the employment or are due to some unexpected result thereof. The term 'and sequelae' frequently used in connection with occupational disease schedules, should be eliminated.

Every one of these suggestions may be found in the compensation laws of one or more of the states; but, the conference board points out, their substantial inclusion in all the state laws would obviate much of the confusion and difficulty now experienced in the administration of these laws."

NOTE—Our readers will please note the quotation marks.

Some Phases of Rejuvenation—The role played by the gonads and the chromatin threads and chromosomes of the cell nucleus of sperm and ovum in the determination of sex is reviewed by William T. Belfield, Chicago (*Journal A. M. A.*, April 19, 1924). He states that in the number of chromosomes of the united sperm and ovum we recognize, not the immutable determination of the sex of the new being, but rather a distinct impulse toward the building of one or the other sex; an impulse that must seemingly be transmitted, as is the distinctive chromosomal structure, to every cell in the body; an impulse which early becomes manifest through the instrumentality of the endocrine glands, including the gonads. This recognition of the fertilized egg as the fundamental factor in sex is essential; it elucidates the otherwise puzzling fact that there is no group of sex features exclusively associated with testis or ovary; and other facts—including possibly homosexuality—inexplicable on the prevalent assumption that sex features emanate from gonads. Defective plans are sometimes manifest in structures deviating from the human type that cannot be explained by human embryology, but which are clearly features of earlier animals in the vertebrate phylum—the so-called arrests of phylogenetic development. The demonstrated difference in cell structure between male and female suggests the possibility that every cell in the body may contribute toward maleness or femaleness; as yet, however, only endocrine glands, including gonads, and cranial ganglions have been proved to make and unmake sex characters. Brown's work indicates that the function of the gonads requires integrity of certain ganglions at the base of the brain, which may be compressed through tumor formation of the pituitary; and that atrophy of the testes may be due to pressure on them rather than to pituitary disease. Among the organs which influence structure and function of the testes must be included certain ganglions at the base of the brain. On the traditional conception that sex emanates from testis or ovary is based the idea that the two sex complexes are essentially antagonistic and immutable. The biologic conception of sex is, on the contrary, not that it comprises two antagonistic entities, but rather that it is a single entity presenting various—and variable—degrees of femininity. There are known many instances in which the female—bird, quadruped or human—has matured normally, and later has assumed in marked degree the features and functions of the male; there is no instance known in which a mature male vertebrate has through intrinsic forces exhibited the corresponding change toward the female type; once a male, always a male; once a female, later a near-male, seems the natural course. Transmutation of females toward maleness, apparently anomalous, is such only in degree; for in all warm-blooded species the heavy burden of reproduction imposed on the female is transitory; and cessation of ovulation is often accompanied by some exchange of feminine for masculine features. Despite the wealth of pertinent observations, clinical and experimental, the influence of gonads on sex character is not yet exactly defined.

Homotransplantation of the human testis should, on biologic data, be more promising than that of the ovary; for these data indicate that the somatic tissues, inherited through the fertilized egg from the entire vertebrate phylum, are in harmony with the ancient maleness, but not with the new femaleness of the placental animals—that they are homologous with the testis, but heterologous toward the ovary. And since, for the structure and maintenance of sex characters, somatic tissues—the endocrines at least—are as essential as are the gonads, the male castrated before maturity may develop partial maleness—thanks to his somatic tissues—while the spayed young female lapses—thanks to those tissues—from femaleness toward maleness. Hence it seems possible, a priori, that a testis transplanted into an otherwise normal young man deprived of the testes might reinforce the maleness of the host's somatic tissues, even though the ovarian transplant into the female fails to do so.

Belfield asserts that Steinach's method of rejuvenation merits little attention; for it is founded on error and refuted by experience. Steinach's theory of rejuvenation—for men at least—falls to the ground. The experimental work of careful investigators on rejuvenation by testis implantation seems to have established these results on animals: Testis transplantation succeeds often in young, rarely in old, animals; success meaning merely the maintenance of vitality for a period of months. Though the transplant never produces sperms in its new host, it may function to the extent of preserving the masculinity of a castrated young male for a limited time, or of causing in a spayed young female hypertrophy of the clitoris and distinctly masculine behavior. The life of the transplant is much shorter than that of the native testis; within a few months its elements are replaced by connective tissue, and its physiologic effect on its host ceases. Stimulation of erection sometimes follows testis transplantation in old men, appearing within a few hours and ceasing within a few days. This is apparently the effect of preformed substances contained in the transplant and absorbed therefrom by the host's tissues. Similar effects have followed the injection of milk. A lasting recovery of lost erectile power in old men through testis transplantation is yet to be demonstrated. The future of testis therapy seems to depend on the isolation of the activating substance produced in the testis corresponding to thyroxin or insulin. Until this shall be accomplished, the injection of an emulsion of testis tissue seems the most promising form, though such a mixture of unknown proteins must be a tentative remedy. It seems probable that gonad therapy begun as an irrational attempt at an impossible "rejuvenation," may emerge from the disrepute of its infancy, and develop into a valuable means for relieving ailments that are not now associated with gonad deficiency; for it is demonstrated that the gonad does not originate sex; that it is less essential to the maintenance of sex than is the thyroid or the suprarenal; and that it is indeed one of a chain of interacting endocrine glands, efficiency in every link of which is essential to normal function, sexual or somatic.

"A Rapid Method for the Determination of Gastric Acidity by Means of Test Papers."—W. Denis, Ph. D., and D. N. Silverman, M. D. (*American Journal of the Medical Sciences*, Jan., 1925, conclude a study of this subject with the statement:

"It is suggested that the customary titrations of gastric contents with Topfer's solution be replaced, at least at the bedside or in the busy clinic by the determination of the hydrogen-ion concentration by means of test papers for which the only equipment needed is a small vial of these papers which may be carried in the pocket."

Specialists have come in for much criticism on the part of the public and even on the part of the general medical profession, as faddists. Yet it must be admitted that specialization has contributed enormously to the advancement of medicine as a whole. It is important, of course, for the prestige of our calling that specialists shall not lose their sense of proportion, and shall base their particular work on as broad a foundation as possible.—DAVID RIESMAN, *A. M. A. Bulletin*.

"The Physical Basis of Unrest—With civilization have come opportunities for the frequent escape from physical labor of those either clever or stupid enough to evade it. Civilization, in fact, expects the clever to dodge it, while the weaklings among the lower orders necessarily escape yet receive considerable paternal care on the part of the society."—*Medical Times*, Jan., 1925.

Properly restricted newspaper publicity of medical meetings, in which personalities are kept in the background, helps to educate the public, and if and when newspaper editors once realize the importance of having medical news carefully edited by a medical co-editor, much of the disturbing misinformation in which our papers now abound, will be avoided.—*A. M. A. Bulletin*.

Physicians' Sterilizers

Every Doctor's office should be equipped with proper sterilizers.

Illustrations show two of the many styles we carry for Sterilizing water and instruments. All our sterilizers can be heated by gas or electric current.

CHICAGO

MEDICAL STRAWS

By THE EDITOR

Experience is fallacious and judgment difficult

Maternity Mortality Increasing—"More women died in childbirth during 1923 than during 1922," says the United States Census Bureau. Later figures are not available. These are discouraging.

J. J. Sippy, M. D., in discussing what a nurse may and may not do, says (Pacific Coast Journal of Nursing) that a doctor "will leave standing orders for hypodermic administration of morphine and strychnia to the student nurse in the hospital and criticize the better-trained public health nurse for administration of toxin-antitoxin, far less dangerous. It causes one to wonder at our inconsistencies."

DOING things for people is harmful misdoing unless it increases their independence, energy and initiative."—Henry Ford.

"Today, the doctor takes the helpful point of view that nervous patients are not office nuisances, but are men and women in trouble: suffering, hoping, thwarted, groping, and crippled," says George K. Pratt (Hygeia). "And because he realizes that a special kind of treatment is needed he refers them to his colleague, the psychiatrist, just as he refers operative cases to the surgeon."

Over 90 per cent of the 100 per cent of people who need a physician's advice are walking about and attempting their duties. If they were adequately and efficiently cared for, our hospitals would be half empty.

THE successful physician is a counselor of health as well as a purveyor of pills.—Henry Shaw (Nation's Health).

DISCIPLINE is the mainspring of action and operation, the first price of successful achievement in any field or forum.—Russell.

Apply it upon yourself in the interests of your patients as thoroughly as you do in your golf.

I SHOULD like to emphasize the fact that even the ordinary practitioner in the smallest village, far from hospital, laboratory or library, can, if he will, make some contribution to medical progress."—C. M. Jackson (National Research Council).

A "sectarian," as applied to medicine is one who, in his practice follows or claims to follow a dogma, tenet or principle based on the authority of its promulgator to the exclusion of demonstration and experience.—House of Delegates, A. M. A.

Quite a satisfying definition.

A physician is one who has acquired a contemporary education in the fundamental and special sciences comprehended in the term "medicine" used in its unrestricted sense, and who has received the degree of Doctor of Medicine from a medical school of recognized standing.—House of Delegates, A. M. A.

Compare that excellent definition with the legal definition of most states and we get a close-up of how government interferes with the progress of health.

PHYSICAL examinations of the well are all right, but they should be performed by the family doctor. This work should not be done second-handed through the

medium of some health institute.—Journal of Indiana Medical Association.

There seems to be a prevalent idea that almost anyone can make a diagnosis of a patient who is walking about.

THE average meal consumed today is the outgrowth of the efforts of cooks who have catered to taste rather than to reason.—N. P. Norman, M. D. (New Jersey Medical Journal).

The Unkindest Cut of All—We don't expect very much any more in this old vale of tears and laughter, but perhaps the hardest thing to forgive the professional reformers is pasteurized cider.—Ohio State Journal.

THE modern business man of the best type has a code of business ethics that might well be adopted by those physicians who are in the medical profession "for what they can get out of it" and not for the amount of service they can render the public.—Edward J. G. Beardsley (New Jersey Medical Journal).

NATURE has not yet adopted union laws and union hours, nor union standardization, and state medicine will have to travel farther and faster than it has been doing to get nature into this set standard.—Illinois Medical Journal.

Professional "Toters" Will Be a New Profession—The lower house of Congress has passed a bill restricting the use of the United States mails for the transportation of firearms that can be concealed upon the person.

One Baby Per Month for Each Doctor—It is announced that 87,000 babies were born in California during 1924. If all of the births were apportioned to educated physicians only, each would have officiated at one birth a month.

SOMEONE has defined an expert as a man who lives 100 miles away and charges \$100 a day for his services.

The quoted "fee schedule" is too low for the "expert" who must pay his publicity agent. And many newspaper editors are growing more discriminating between "news" and "advertising."

THE heart of a man has not capacity enough to feel as a mother feels at the grave of her son," says a proverb.

Nor has he the consolation of such close communion with Him who said "Suffer little children to —"

QUACKERY and the love of being quacked are in human nature as weeds are in our fields."—John Brown.

Weeds—and quackery—grow best on the golden grain fields, the sun-kissed fruit plains, and the breeze-bathed shores of the mighty Pacific. Love of being quacked grows in inverse ratio to intelligence.

MEMBERSHIP in a county medical society is a badge by which the general public determines whether the physician is interested in his colleagues, interested in keeping abreast of modern advances in medicine, and interested in an unselfish protection of community health (Ohio Medical Journal).

Doctors, that is worth reading again, pondering and measuring ourselves by.

THAT commercialized prostitution is the principal means of disseminating syphilis and gonorrhea is emphasized by many popular "health educators."

INFANT DIET

MATERIALS

THE DOCTOR'S METHOD

of

Milk Modification For Infants

Every physician has a method of feeding infants under his care. Much depends on his instructions being carried out.

The Mead Johnson Policy prevents outside interference and doctors find that Mead's Dextri-Maltose, cow's milk and water, gives gratifying results in the majority of infants under their care.

THE MEAD JOHNSON POLICY

Mead's Infant Diet Materials are advertised only to physicians. No feeding directions accompany trade packages. Information in regard to feeding is supplied to the mother by written instructions from her doctor, who changes the feedings from time to time to meet the nutritional requirements of the growing infant.

Are You Reading **BETTER HEALTH?**

OST newspapers, magazines and publications of every sort are now featuring alleged Health Education, Public Health, and even the practice of medicine by mail, as one of their functions. Of the few magazines that are producing worthwhile informative publicity in this field, **BETTER HEALTH** is the oldest. This magazine is owned and conducted by physicians and devoted entirely to improving the knowledge of the general public on matters pertaining to the promotion, conservation and protection of health; and it is one of the exceedingly small number presenting sound and authoritative health information of the same general type that the physician gives to his patients and friends. A copy should be on the table in your reception room at all times. Every physician, at least in the Western States, should be a subscriber to **BETTER HEALTH Magazine**. It needs your support for many and obvious reasons. If you are not a subscriber, please cut out the coupon and mail it at once. Suggest to your patients that they also subscribe.

To **BETTER HEALTH**, Balboa Building, San Francisco

Please send me **BETTER HEALTH**, the monthly magazine with the Daily Health Service, beginning with the March issue, 1925. Upon receipt of magazine and bill, I will send you \$3, payment in full, for one year's subscription.

TRUTH ABOUT MEDICINES New and Non-official Remedies

(Abstracts from reports of Council on Pharmacy and Chemistry, A. M. A.)

Note—These do not represent all of the actions of the Council, but they do represent those remedies manufactured by firms who co-operate with CALIFORNIA AND WESTERN MEDICINE in its advertising columns, and thereby with the physicians in California.

In addition to the articles enumerated in our last report, the following have been accepted:

Hynson, Westcott & Dunning—Antimony Sodium Thioglycollate; Antimony Thioglycollamide.

Eli Lilly & Co.—Iletin (Insulin—Lilly) U-10, 10 cc.; Iletin (Insulin—Lilly) U-20, 10 cc.; Iletin (Insulin—Lilly) U-40, 10 cc.

Parke, Davis & Co.—Iron Citrate Green: Ampules Iron Citrate Green (P. D. & Co.), $\frac{1}{4}$ grain; Ampules Iron Citrate Green (P. D. & Co.), $\frac{3}{4}$ grain; Ampules Iron Citrate Green (P. D. & Co.), $1\frac{1}{2}$ grain; Mercurettes; Proposote: Proposote Capsules, 5 minims; Proposote Capsules, 10 minims.

Bacillus Bulgaricus (Squibb)—A culture of Bacillus Bulgaricus, marketed in tubes, each containing 12 cc. Bacillus Bulgaricus (Squibb), is designed for internal administration and for direct application to body cavities, abscesses, and wounds. See "Lactic Acid-Producing Organisms and Preparations," New and Non-official Remedies, 1924, p. 169. E. R. Squibb & Sons, New York.

Proposote—A condensation product of creosote and phenylpropionic acid. It contains the equivalent of 50 per cent of creosote. Proposote is not decomposed by the gastric fluids, and passes the stomach practically unabsorbed. It is decomposed in the intestine, and its components are chiefly eliminated through the kidneys, but it is claimed that a part of the liberated creosote is eliminated through the respiratory tract. Based on this latter elimination, the administration of proposote is claimed to

be of value in bronchitis and coughs due to bronchial infections. Proposote is used for the same purposes for which creosote is administered. It is marketed in the form of capsules containing 5 and 10 minims, respectively. Parke, Davis & Co., Detroit.

Antimony Sodium Thioglycollate—A compound formed by dissolving antimony trioxide in a solution of a mixture of sodium thioglycollate and thioglycollic acid. It contains not less than 37 per cent of antimony. The actions and uses of Antimony Sodium Thioglycollate are the same as those of Antimony Thioglycollamide, but it is more soluble, and in higher doses appears to be less toxic. Hynson, Westcott & Dunning, Baltimore.

Does the Shoe Fit?—"If we do not give to each patient who consults us our best services, we lower our standard, as well as aid in lowering the standard of medicine in the city or town in which we are licensed to practice," is the belief of E. J. G. Beardsley (New Jersey Medical Journal). "One of the greatest deterrents from doing our best professional work is that we *do not make careful physical examinations*. The failure to provide office kimono or similar covering is frequently made an excuse for not carrying out the complete examination that should be made of our female as well as our male patients."

The Future of Physiotherapy—"I see a great future for physiotherapy," says Ray Lyman Wilbur (P. T. Review), "if it is maintained and associated with the best that medicine offers in other fields. If it becomes simply one of the so-called cults, if the workers in it place an undue importance upon it and think they can, by using these procedures, neglect those necessarily diagnostic methods or proper professional care, then this, for the present, will again go into disrepute. But if this is kept on a clean, clear, scientific, intelligent, therapeutic basis, it has an enormous future of service to the public, as well as of help to those practicing medicine."

Experts go to Experts

Men who are expert in their profession are usually the first to appreciate the value of expert counsel and service in other fields than their own.

Then why do so many professional men endeavor to look after their own investments? Surely a bond purchase—involving intricate credit considerations—is work for experts.

It is a comparatively new Trust Company service which relieves the professional man of the burden and responsibility of watching over his investments—and therefore is not widely understood.

The Wells Fargo Union Safe-keeping Account—a special service for professional men—is described in our new folder, No. A-14.

May we send you a copy?

"BETTER HEALTH" Embodies This Principle—
"Those who have the public health in view and want to succeed in this contest will have to make a more vigorous fight. They must organize to educate the people and to inform legislators," is the opinion of H. E. Kelly, a prominent member of the Chicago bar (Federation Bulletin). "They must spend their time and money more freely in presenting the public's cause to the legislators of the country, and, indeed, to the courts, too, which also require ample arguments on the cases before them. *The persistent, the vigilant, the crusading men win.* It is unfortunate that truth has to be thus enforced and that it is not self-evident. But error propagated by money, enthusiasm and a not too scrupulous regard for facts often—in some fields generally—overcomes truth, which thus crushed to earth only after a long period of time will rise again. *Those who would give the public better health laws, if they would succeed, must not be content with merely stating their case scholastically, but they must organize to propagate it and then enforce it and compel attention to it by the practical methods everywhere influential with men, not only today, but tomorrow and year after year, until the truth is permanently embodied in the law as the settled policy of the state.*"

The Purpose of Medical Education—"The purpose of medical education," as E. H. Ochsner sees it, "is to provide for the present and future citizens of the country the best medical care, service, and attention that is possible under the circumstances. We are not doing this today. And we are not likely to do this until we realize the faults in our present system of medical education. Just now the story is making the rounds that there is a shortage of medical men. Nothing could be further from the truth. The fact is that the medical profession as a whole, and particularly of the cities, is greatly overcrowded."

When wise men play the fool they do it thoroughly.—
Italian Proverb.

ILETIN (INSULIN, LILLY)

Pure, Stable, Constant in Unitage

A Larger Package at a Slightly Lower Price

Iletin (Insulin, Lilly) is now supplied in containers of two sizes: 5 c.c. vials and 10 c.c. vials. Both the 5 c.c. and 10 c.c. vials bear the same designation: U-10, U-20 and U-40. To distinguish between the two sizes it will be necessary, for example, to order as U-10—5 c.c. vials or U-10—10 c.c. vials. In absence of specifications as to size wanted, the 5 c.c. vials will be supplied.

The price of Iletin (Insulin, Lilly) in 10 c.c. vials is slightly lower than that in 5 c.c. vials due to economies in packaging.

IMPORTANT ACCESSORIES

Iletin Syringes, Urine Sugar Testing Outfits, Saccharin Tablets, Ampoules Glucose, Benedict's Solution, Plain Agar Granular. Send for additional information on these items.

All Lilly Products are Supplied by the Drug Trade

Petrolagar

**A palatable, non-irritating emulsion
of pure mineral oil and
agar-agar**

In PETROLAGAR the physician is afforded a preparation in which mineral oil and agar-agar are combined in a pleasant-tasting and efficient product for the treatment of constipation.

The agar is specially prepared so as to yield on incubation in the intestinal tract very many times its original bulk, forming a bland, gelatinous mass which gives the bulk necessary for the healthy peristaltic action of the bowel muscle, without irritation.

The mineral oil is so finely diffused with the agar-agar that it thoroughly mixes with the fecal matter, gives full lubrication and thus diminishes the annoyance of leakage accompanying the use of oil in the older forms.

The pharmaceutical methods by which PETROLAGAR is prepared are such that there is no taste of oil whatever. In fact, this elegant pharmaceutical product has the appearance and taste of pudding sauce and can be taken by even the most fastidious patient without any objection or danger of eructation.

The action of PETROLAGAR being entirely mechanical, does not interfere with any other medication which may be administered at the same time.

PETROLAGAR is issued as follows: PETROLAGAR (Plain); PETROLAGAR (with Phenolphthalein); PETROLAGAR (Alkaline); and PETROLAGAR (Unsweetened, no sugar).

PETROLAGAR has been accepted for New and Non-Official Remedies by the Council on Pharmacy and Chemistry of the American Medical Association

There is a splendid opening for competent X-Ray men.

A few desirable offices now available.

Prevention of Congenital Syphilis by Treating Mother During Pregnancy—Some data on the results obtained by treating women during the child-bearing period, recently collected from eighteen municipal clinics of this state, are offered by Joseph S. Lawrence, New York (*Journal A. M. A.*), as evidence of the great benefits to be derived from careful treatment of ambulant patients at public clinics or dispensaries. Fairly complete data were obtainable on seventy-six cases, in all but one of which the patients, since beginning treatment, either have given birth to children or are now pregnant. Eleven women came for treatment before or during their first pregnancy. The sixty-five who had pregnancies prior to coming to the clinic may be divided into two groups: Eighteen (38 per cent), which we shall designate as Group A, were childless, while the other forty-seven (62 per cent), which we shall designate as Group B, had living children when treatment was begun. The primiparas were each, with two exceptions, delivered at full term of an apparently healthy normal child. None of these children exhibit any syphilitic stigmas, although some are more than a year old. The two exceptions were in abortion, which was found to have been artificially produced, and one pregnancy not terminated when the data were collected. In one instance in which therapy was instituted before marriage three pregnancies have resulted in the birth of three children, all of whom are free from any symptoms of syphilis. The eighteen multiparous women who had no living children when they began treatment have each, with four exceptions, had a child apparently free from congenital infection. The exceptions include two incompleted pregnancies, one fetal

death from dystocia and one miscarriage attended by hemorrhage which proved fatal to the mother. These eighteen women, who before receiving anti-syphilitic treatment were childless in spite of fifty conceptions, have had fifteen living children from seventeen pregnancies since treatment was begun. The forty-seven multiparous women who before taking treatment had 114 living children from 260 pregnancies have had subsequently fifty-four conceptions, eight of which have not been terminated. These forty-six pregnancies resulted in thirty-eight living infants, eight abortions, miscarriages or stillbirths and six infant deaths. Three of the five interruptions were miscarriages occurring in two women who were careless about their attendance at the clinics and received very unsatisfactory treatment. Of the six infant deaths, two were twins and a third was one of twins; while their deaths may have been due to syphilis, it must be remembered that the infant mortality for twins is greater than for single births. There were three sets of twins in this series. The scheme of treatment which the clinics employ consists of eight intravenous injections of arsphenamin given at intervals of a week, and fifteen intramuscular injections of mercury, also at intervals of a week; while treatment with arsphenamin and mercury are carried on simultaneously, they are rarely administered on the same day, but are separated by a three or four-day interval. After the fifteen injections of mercury are completed, a rest period of a month or six weeks is permitted, and then the procedure with both drugs is repeated. The size of the dose of arsphenamin is gauged by body weight, 0.1 gm. being allowed for each thirty pounds, (13.6 kg.). The mercurial preparation most commonly in use is mercuric salicylate, and the average dose is 1 grain (0.065 gm.).

It's the physician that breaks the rules of health.—Japanese Proverb.

Complete Transposition of the Viscera—Twenty-nine cases of complete transposition of the viscera are reported by Leon T. LeWald, New York (Journal A. M. A.). Complete transposition of the thoracic and abdominal viscera seems to be more common than is generally believed. Transposition does not impair the health of the individual. It should not bar him from military service, nor should it in any way alter his status relative to life insurance. Rotation of the heart on an axis, sometimes described as dextro-cardia unassociated with transposition of the viscera, is entirely separate from transposition and is a very rare condition. LeWald has encountered only one case. Retraction or displacement of the heart can always be distinguished roentgenologically from transposition or rotation of the heart. Non-rotation of the colon should never be confused with transposition of the viscera, from which it can always be distinguished by a roentgen-ray examination. Cecum mobile is due to excessive descent of the cecum and is frequently wrongly diagnosed as chronic appendicitis. A combination of two or more of these conditions may be present in the same individual; for example, failure of the colon to rotate in a person with complete transposition of the viscera will leave the appendix on the right side, while the heart and stomach are also on the right side. LeWald urges that extreme care be taken to so mark all roentgenograms that the right or left side of the body can be unmistakably identified.

Modern advertising has become a powerful force that is hardly reconcilable with the old bally-hoo type of publicity known to a former generation and which included all the evils known to the profession. Still, it has been a healthy growth and we have seen the ugly duckling nursed through all the handicaps of childhood until today, while still susceptible to some of the mischievousness of youth, it stands forth a finished product, a recognized profession symbolizing an absolute business necessity.—H. J. Donnelly, Jr. (The Annals).

Human Milk—The commercial production of human milk and its distribution in containers direct to the home have passed through the experimental stage. R. Raymond Hoobler, Detroit (*Journal A. M. A.*, January 17, 1925), reviews the work done in that direction in Detroit, since 1916. The actual output during this eight-year period has been 414,242 ounces of human milk, approximately 13,808 quarts. The present overhead expense could care for handling 100,000 ounces yearly, which would bring the cost of production to 10 cents an ounce. The cost of production includes the amount paid the mother, which is a flat rate of 10 cents an ounce, plus the cost of carfare for coming to the bureau either to express the milk or to deliver it in bottles. The remainder is overhead. The bulk of the money to pay the cost of operation comes from private patients who have been referred to the bureau by pediatricians and the medical profession generally. The bureau occupies quarters in the Woman's Hospital and Infants' Home, of which it is an integral part, and is operated under the direction of a committee from the hospital board and representatives of the Detroit Pediatric Society. The bureau employs two full-time officers. The maximum price charged was 30 cents an ounce. This charge is made only when it involves no hardship. In cases in which the milk is needed and the parents are unable to pay the maximum price, the charge is scaled down to their paying ability; but in no case is a baby denied milk. Some mothers have raised as many as three consecutive babies on the milk furnished by the bureau. The bureau keeps a sufficient number of producing mothers on its payroll to supply more than enough to cover its needs for private cases. This excess, each twenty-four hours, is distributed free of charge to hospitals caring for sick and premature infants. Should calls come in from private patients, this excess is drawn upon, and not so much milk is available for free distribution. Producers come mainly in answer to advertisements in the daily press. Others come by reference. Not all that apply are found satisfactory. They must come up to a certain rigid standard. They must: (1) be healthy, have a nega-

tive Wassermann reaction and be free from tuberculosis; (2) have clean personal habits; (3) live in a clean home; (4) nurse their own healthy babies up to 8 months; (5) express milk at least twice daily; (6) keep milk on ice until delivered, and (7) supply at least 16 ounces daily. A mother who has been at the bureau during three lactating periods, extending over fourteen months, had an income from the bureau of more than \$3500. This so encouraged her that when the bureau refused, after the fourteenth month, longer to use her milk, she purposely became pregnant that she might again become a producing mother. She is again at the bureau earning a good income, which is enabling her to buy her own home, and, incidentally, to enjoy many comforts previously beyond her reach. The bureau does not stipulate the diet the producing mother should use, but recommends one with a narrow protein ratio which was found to be most suitable. Any article causing an odor to the milk is strictly prohibited. The greatest percentage of infant mortality is among premature and sickly infants, during the first one or two months of life. Breast milk, if available, would save many of these lives. At present, there seems to be no satisfactory substitute for breast milk at this early age, particularly if the infant is a weakling; and there seems no better way to reduce the mortality of this early period of life than to increase the production of human milk. Every community supporting a maternity hospital is a potential center for such a producing group.

About Defective Eyesight—Perhaps we have become unduly pessimistic. In recent tests made by officers of the United States Public Health Service for defective vision on approximately 10,000 school children in four Eastern localities, 63 per cent of these young persons, ranging in age from 6 to 16 years, were found to be normal in both eyes; only 10 per cent had rather poor vision in one or both eyes. Nature's equipment of man for vision is, therefore, not as imperfect as a hasty guess might suggest.—*Journal A. M. A.*

Mary's Help Hospital and School of Nursing

145 GUERRERO ST., SAN FRANCISCO, CALIFORNIA

Pituitrin

THE ORIGINAL PITUITARY EXTRACT

PITUITRIN was the first preparation of its kind ever used in obstetrics as an aid in labor. It is a standard product employed the world over in uterine inertia, and for other definite indications as well.

Among pituitary extracts Pituitrin should be preferred because it is always the same. Every lot is doubly tested—for its effect on blood pressure and for its effect on uterine muscle. What the physician wants in a preparation of this kind is not excessive activity, but uniformity so that he may avoid both the danger of an overdose and the embarrassment of ineffectiveness.

In addition to the security afforded by double standardization, every package of Pituitrin is dated.

These advantages are yours if you specify on your orders for pituitary extract "Pituitrin, P. D. & Co."

If Surgical Pituitrin is wanted specify Pituitrin "S." This preparation is twice the strength of Pituitrin—1 cc equivalent to 2 cc of the latter. Pituitrin "S" is not recommended for obstetrical use.

PITUITRIN and PITUITRIN "S" are supplied in liquid form only, in ampoules, six to the box—Pituitrin in 1-cc and 1/2-cc ampoules; Pituitrin "S" in 1-cc ampoules only.

Ask for our booklet "Pituitary Therapy"; requests from physicians are welcomed and gladly complied with.

The Hartung Hospital Silent Call Signal System

SAFE—SILENT—SIMPLE

Calling Station No. 106

The calling station herewith illustrated shows one of the sixteen combinations that we have to offer.

This station consists of the control switch with ball chain, slip connector, pull cord and pear shaped pendant attached. A slight pull on the cord illuminates a red lamp over the door in the room visible to the patient, over the door in the corridor, a red pilot lamp in the diet kitchen and utility room, and the lamp in the annunciator which shows the number of the room calling. These lamps continue to burn until the call is answered and the control switch knob restored to the off position by the nurse.

The push and pull Emergency Switch is used by the nurse only when she finds the patient in a critical condition and needs immediate assistance. The nurse, pulling out the button of the Emergency Switch, illuminates a green lamp in the corridor over the door of the room, a green pilot light in the superintendent's office, at the nurses' station and wherever desired. This Emergency call is restored, when answered, by pressing the button of the switch which extinguishes all the green lights. If desired an audible buzzer may be connected to the emergency switch.

The Radio jacks shown are of the cord tip type and furnish a connection for radio head sets for the reception of radio broadcasting. The radio receiving set being located in the office or wherever desired.

Illustrated booklet and detailed information upon application.

The Services of our Engineers are at your disposal.

Heart Station

A laboratory for the investigation of Cardiac conditions.

As we are equipped with highly specialized apparatus, in particular an instrument for determining the exact angle in which the patient is being examined, we believe we are enabled to give the heart and especially the Aorta a more than ordinary accurate examination.

An outline of our routine examination is as follows:

- (I) a. History.
b. Complete Physical Examination.
c. Heart Function Tests.
d. Kidney Function Tests.
e. Vital Capacity, etc.
- (II) X-RAY EXAMINATION
a. Pictures in Frontal Position.
b. Pictures at various angles.
- (III) FLUOROSCOPIC EXAMINATION
a. Study of the comparative size and shape of the different Cardiac chambers.
b. Measurement of the Anterior-Posterior size of the heart, frequently the first part to show enlargement.
c. Orthodiagram and Cardiac Pattern—the latter to be used in checking up your own physical findings.
d. An attempt to judge the quality of the heart muscle and determine its probable efficiency and reserve power.
e. Careful measurement of the Ascending and Descending Aorta.
- (IV) ELECTROCARDIOGRAPHIC STUDY
Almost indispensable as a diagnostic aid in many Cardiac conditions.
- (V) METABOLISM TESTS, ETC.
In all cases a detailed and comprehensive report is furnished which will include diagnosis, prognosis and suggestions.
No stay in the hospital is required.
Any single test or examination can be asked for.

ALBERT SOILAND, M. D. WM. E. COSTLOW, M. D.

Recovery From Subacute Infective Endocarditis Following Gentian Violet Therapy—Ralph H. Major, Kansas City, Kan. (Journal A. M. A.), cites the case of a woman, aged 25, with subacute infective endocarditis who made prompt recovery following intravenous use of gentian violet. The patient had a positive Wassermann reaction, and for this reason was given potassium iodid in gradually increasing doses, for a period of ten days. At the end of this time, there was no change in the patient's condition and she was still showing fever. The blood culture showed the streptococcus present in the blood stream. The same day, the patient was given intravenously 5 mg. of gentian violet per kilogram of body weight, in a 1:500 aqueous solution. Forty-eight hours after the first injection, the temperature was normal. A blood culture was taken and found to be sterile, and the patient was given another injection of gentian violet intravenously forty-eight hours later. A second blood culture was also negative, and the two subsequent blood cultures, while the patient was in the hospital, showed no growth. The patient received, in all, four intravenous injections of gentian violet. Since her discharge from the hospital, she has had three negative blood cultures. During one of the intravenous injections of gentian violet, the dyestuff extravasated into the tissues and set up a necrosis, which produced some sloughing and considerable discomfort to the patient. This cleared up, however, without any severe complications.

We ought not to imitate the good mariner who out of covetousness loads his ship hard and afterwards labors hard to throw out the salt water, by first clogging and overcharging our bodies and endeavoring afterwards to clear them by purges and clysters; but we ought to keep our bodies in right order, that if any time they should be oppressed, their lightness may keep them up like a cork.—*Plutarch's Rules of Health.*

ANNOUNCEMENT

OUT OF TOWN PHYSICIANS ARE CORDIALLY INVITED TO ATTEND CLINICAL DEMONSTRATIONS OF THE MORE IMPORTANT UROLOGICAL DISEASES. ARRANGEMENTS ARE AVAILABLE FOR THE EXAMINATION, STUDY AND TREATMENT OF CASES WITH CYSTOSCOPIC DEMONSTRATIONS. A COURSE IN CYSTOSCOPY WITH URETERAL CATHETERIZATION, KIDNEY FUNCTIONAL TESTS, PYELOGRAPHY, FULGURATION OF BLADDER TUMORS, ETC., WILL BE GIVEN.

Increasing
the
Nutritional
Yield
of
Milk-
23%

THE protective colloidal ability of pure, plain gelatine, in preventing the curdling of milk by the enzyme rennin and hydrochloric acid of the gastric juice, is one of the most important discoveries relating to milk nutrition.

Thomas B. Downey, Ph. D., of Mellon Institute, University of Pittsburgh, has determined by standard feeding tests that 1% of pure, plain gelatine, dissolved and added to milk, increases the nutritional yield by about 23%.

The standard formula used by Dr. Downey for infants is as follows:

Soak for ten minutes one level tablespoonful of Knox Sparkling Gelatine in $\frac{1}{2}$ cup of cold milk taken from the baby's formula; cover while soaking; then place the cup in boiling water, stirring until gelatine is fully dissolved; add this dissolved gelatine to the regular formula.

For children and adults follow the same method, but in the proportion of $\frac{1}{2}$ teaspoonful of gelatine to a glass of milk.

In infant feeding the gelatine may be added to any regular formula prescribed by the physician.

To safeguard against impurity and disturbing acidity it is essential to specify Knox Sparkling Gelatine, the Highest Quality for Health.

A package of Knox Sparkling Gelatine, together with the physician's reference book of nutritional diets with recipes, will be sent free to any physician, upon request, if he will address the Knox Gelatine Laboratories, 417 Knox Avenue, Johnstown, N. Y.

An African Holiday. By Richard L. Sutton, M. D. The C. V. Mosby Co. St. Louis.

Rejuvenation, the work of Steinach, Voronoff, and others. By Norman Haire, Ch. M., M. B., New York: The Macmillan Company. 1925.

Serum Prophylaxis of Epidemic Parotitis—In two exposed groups of children in a contagious disease hospital, J. C. Regan, Brooklyn, N. Y. (Journal A. M. A.), first attempted convalescent serum immunization as a protective measure against epidemic parotitis. The protection afforded, although the exposure was close and the contact intimate, has been complete in this series of cases. The results gave reason to believe that the convalescent serum prophylaxis may be just as applicable to this disease as it is to measles. Immunization was effected with an average injection of 3 cc. of convalescent serum within a period varying from the first to the sixth day after exposure. Only one of the eighty-one patients developed mumps; but eleven were discharged from observation before their possible incubation period was over, and the results in these eleven immunized patients are not known. The remaining sixty-nine showed no signs of the disease. The convalescent blood used for this immunization was taken from healthy adult donors, who were Wassermann negative and clinically free from any active signs of tuberculosis, between the extremes of the tenth and twentieth day, usually on the fourteenth or sixteenth day of their disease. The serum should be administered before the seventh day after exposure to afford complete immunity. The dosage should be between 2 and 4 cc.

F several reasons for our rapidly growing business, here are two:

Users of Riggs Prescription service *continue* to be our patrons.

And present patrons boost our service to their many professional friends.

Announcement

A stock of surgical instruments (featuring Eye, Ear, Nose and Throat), is now being carried at our San Francisco and Los Angeles houses. This is merely one of the many features which go to make our service a complete one for the Ophthalmologist.

LOS ANGELES

RADIUM THERAPY

An adequate quantity of radium and complete emanation apparatus affords the facilities essential for modern technique in radium therapy.

DEEP X-RAY THERAPY

Two complete 300,00-volt installations providing every facility for preliminary and post-operative Radiation and X-ray Therapy alone or in combination with other treatment.

X-RAY DIAGNOSTIC LABORATORIES

Completely equipped offer the profession every assistance for roentgenology as an aid in diagnosis.

HOSPITAL AFFILIATIONS

Including a complete high voltage X-ray and Radium Therapy department in the Methodist Hospital amply provide for cases requiring hospitalization.

LABORATORIES

Affiliated for clinical and pathological study and complete facilities for Actinic Ray Therapy.

This institution possesses unexcelled facilities for radium and radium emanation therapy and high voltage X-ray therapy. With modern X-ray diagnostic, clinical and pathological laboratories, complete equipment for electric coagulation, cautery and allied surgery, it offers the medical profession unexcelled facilities for the diagnosis and treatment of neoplastic diseases.

We desire to confer and co-operate with the Medical Profession in the treatment of cancer and other appropriate diseases and request inquiries either in person or by correspondence.

E. D. Ward, M. D.

REX DUNCAN, M. D., Medical Director

What Is the Answer?—With regard to nursing, a very difficult situation has arisen which it is essential that this society should attempt to solve. A type of nurse has been evolved which, while very valuable in public health work, is becoming more and more unsuited to the bedside tasks that are the essential features of her profession. Drawn from the better educated classes, the nurse of today is unwilling to perform the more menial tasks that are assigned to her, and frequently, when stationed in a home where there is sickness, requires for herself a service and attention that are an additional burden to a family already disrupted by illness.—Samuel J. Kopetzky.

So, too, for Syphilis and Many Other Diseases—“The evidence is overwhelming (Journal A. M. A.) that, when tuberculosis is introduced into a country hitherto free from it, the natives manifest a degree of resisting power much inferior to that shown by inhabitants of countries in which it has been present for countless generations.”

There are vast communities in the world so thoroughly “syphilized” that the primary lesions are rarely seen, the “secondaries” are slight or absent, but the more remote consequences of the disease are markedly prevalent.

Where Beginneth and Endeth Religion—When the occupation of healing the sick is carried on as an occupation for hire, regardless of the spiritual or material form of the curative agent, it may not logically be considered entitled to any special privilege or exemption on the ground that it is the exercise and enjoyment of religious profession or worship; no more than shipping misbranded foods in interstate commerce may be made the basis of an exemption from prosecution on the ground that this sort of business is pursued as an exercise of the defendant's religious tenets. Even religion must begin and end somewhere.—H. E. Kelly of the Chicago bar.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.
2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.
3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.
4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.
5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

SPECIAL ARTICLE

THE FUNCTION OF THE SPLEEN

By H. A. HALL, M. D., AND E. ABLAHADIAN, B. Sc.,
Glendale, California

AT LEAST UNTIL WE KNOW MUCH MORE THAN WE NOW DO OF THE SUBJECT, AN OCCASIONAL REVIEW OF OUR KNOWLEDGE OF THE FUNCTIONS OF THE SPLEEN IS WORTH WHILE. WHEN TO SUCH A REVIEW IS ADDED SOME APPARENTLY IMPORTANT AND CAREFULLY CONDUCTED RESEARCH, THE SUBJECT IS ENTITLED TO PROMINENCE.

IN OFFERING THIS ARTICLE FOR PUBLICATION, DOCTOR HALL STATES IN HIS LETTER OF TRANSMITTAL:

"UNDER SEPARATE COVER, I AM FORWARDING AN ACCOUNT OF SOME ORIGINAL WORK PERFORMED BY MYSELF AND A COLUMBIA GRADUATE CHEMIST. I BELIEVE THAT THE RESULTS OF OUR WORK ARE BOTH INTERESTING AND PRACTICAL, AND THROW, AT LEAST, A FEW RAYS OF LIGHT UPON THE TRUE FUNCTION OF THE SPLEEN.

"MISS ALBAHADIAN, WHO WORKED WITH ME CONTINUALLY THROUGHOUT THE EXPERIMENTS, GRADUATED FROM CHEMISTRY AT COLUMBIA, IN 1917, HAD TWO YEARS OF POST-GRADUATE WORK IN CHEMISTRY AT CORNELL UNIVERSITY, AND HAS PERFORMED HIGHLY SATISFACTORY WORK IN SEVERAL PRIVATE LABORATORIES IN CALIFORNIA.

"I GRADUATED FROM ALFRED UNIVERSITY, A BRANCH OF THE UNIVERSITY OF THE STATE OF NEW YORK, IN 1915, WITH A BACHELOR OF SCIENCE DEGREE, AND LATER TOOK UP MEDICINE, GRADUATING FROM THE COLLEGE OF MEDICAL EVANGELISTS IN 1920. SINCE GRADUATION, I HAVE BEEN IN ACTIVE GENERAL PRACTICE AT RIVERSIDE, WITH THE EXCEPTION OF THE PAST TEN MONTHS, DURING WHICH TIME I HAVE BEEN IN GLENDALE, CALIFORNIA. I AM A MEMBER OF THE COUNTY, STATE, AND NATIONAL MEDICAL SOCIETIES.

"IF YOU CARE TO READ THIS ARTICLE, WE SHALL BE PLEASED, AND IF YOU DECIDE TO PUBLISH IT IN PART, OR IN WHOLE, IN CALIFORNIA AND WESTERN MEDICINE, WE SHALL, OF COURSE, BE GREATLY PLEASED.

"WE SEND THE ACCOUNT OF OUR WORK TO YOU WITH THE IDEA OF SPREADING THE PRACTICAL INFORMATION WHICH WE FELL UPON BY ACCIDENT AND DEVELOPED BY MUCH HARD WORK."—EDITOR.

*T*HERE is just one finding in common in all the list of conditions that are known to have splenic hypertrophy, or splenomegaly, so-called.

The spleen may have something to do with hemolysis; it may have something to do with the elaboration of uric acid; it possibly is an important lymphatic gland, but, above all these functions, we wish to place its action as a calcium metabolism stimulant, preparing suitable calcium salts for presentation to the blood stream and the impoverished body cells.

12 centimeters; breadth, 7 centimeters; thickness, 4 centimeters; and that its weight is approximately 160 grams, would be repeating facts that can be readily found in all of our standard anatomy books.

Let us, for a moment, look over the possibilities that the spleen has had in the field of medicine from the supposititious standpoint entirely. This organ was supposed to have something to do with the elaboration of iron, probably set free after the demolition of the red corpuscles. This gland was also implicated for a time in the production of uric acid. A digestive function was also attributed to the spleen and its hormones, for it was observed, in some instances, that the gland enlarged after meals, reaching its maximum at approximately the fifth hour after eating. Enlargements of the spleen have been observed in practically all of the fevers, especially those of the intermittent type.

Mr. Raymond Householder of Chicago, in 1921, experimented with guinea pigs, and in a long series

THE authors of this article had for some time felt that the spleen must have some worthwhile function, and set to work about a year ago to carry out some very definitely planned campaigns into the splenic area to see if the spleen were worth anything, and, if so, for what.

A great deal has been written about the spleen, pro and con. Many functions have been attributed to it and it has been endowed with all sorts of possibilities, as, for instance, a graveyard for the red blood-cells; also as one link in the lymph glandular chain. The upshot of the whole matter has been that, for a long time, the only definite thing known about the spleen was its average size, weight, and anatomical position in the body. For us to state, for instance, that its average length is

of cases found that the subcutaneous injection of hydrochloric acid caused splenomegaly. This author and experimenter, in his conclusions, infers that this enlargement could possibly be due to the increased destruction of red cells which must accompany this artificial acidosis, and yet wavers also toward the belief that the gland was perhaps hyperfunctioning as a hematogenic gland to offset this same anemia.

Other experimenters (Ott and Scott of The Medical Chirurgical College of Philadelphia) have tested certain of the animal extracts, as well as other drugs, and their influence upon splenic size. Infundibulin (pituitrin) was shown to decrease primarily the volume of the spleen and then to cause an exaggeration in its size. No relation between blood-pressure changes and splenic size was demonstrated. Pineal solution was tested and found to cause a diminution in the size of the spleen, after which the gland returned to normal. Thymic infusion had the same action, as did also infusion of the ovaries. Corpus luteum in solution produced an increased volume in the gland, which shortly became normal. Infusions of mammary tissue and dried pancreas had no action upon splenic volume. The results from injections of quinin hydrochloride were not of a nature to establish any definite reports, for, in some instances, the spleen increased, and in others decreased in size. Probably all of the above changes can be explained from blood vascular changes of the vasomotor type, as, for instance, when adrenalin or infundibulin were used.

Can we say, then, that the spleen has an internal secretion or hormone? Does it break up red cells because of a true hormone or because of a secretion of the digestive type that breaks down red blood corpuscles or disease germs, as the case may be? Can we not explain some of its functions by stating that it produces phagocytes which devour invading organisms and by a rapid elaboration on the part of the splenic laboratory may fill the blood stream with a normal amount of white cells in ordinary existence and an overamount in certain of the lymphatic leukemias, for in such cases we find a splenomegaly? Whether this action of the spleen in relation to blood cells is endocrine or not we may never be able to state, but we do know that the results of splenectomy are very satisfactory in certain splenic anemias and in hemolytic jaundice.

Inlow, at the Mayo Clinic, some years ago carried out a series of experiments to show the effects of splenectomy upon digestion, with particular reference to the flow of bile and the production of bile acid. He concluded that there is an increase in the outflow of bile after splenectomy, constituting an amount about one-fourth above that produced in the normal animal. The findings vary, however, when the time element is considered. Shortly after splenectomy, there is an increase in the output of bile, and along with this there is a concomitant rise in the hemoglobin content of the blood, and also in the red blood-cell count. All of this is later followed by an anemia and a reduction in the amount of hemoglobin, with more or less change in the flow of bile, usually more readily observed in late cases. His most dependable finding was that the regular fluctuation in the flow of bile and in the blood condition is accentuated by splenectomy.

Whether these findings are practical or not, we are unable to state. They are of academic interest at least. Other investigators at the Mayo Clinic have shown that the spleen may at times serve as a reservoir for the retention of syphilitic spirochetes, and, just for the moment, it is pleasing to know that the removal of such spleens is attended by a rapid change for the better on the part of the patient. Things may turn for the worse later, but, in many instances, there is an apparently satisfactory result following splenectomy in these individuals. This same clinic removed a large series of spleens in pernicious anemia, but the results were so discouraging that the procedure has been discontinued for the relief of this particular disease.

Dr. Reginald Weiler, of New York City, has given us an exhaustive discussion of the so-called spleno-pancreatic apparatus, and his conclusions would evidently show that it has a definite relation to the endocrine apparatus in general. The relation of the circulation to both glands is such that he believes that trypsin should be called the spleno-pancreatic secretion (a true internal secretion), "which reaches the portal vein by the way of the splenic vein and which continues in the blood stream the splitting process begun in the intestinal canal." That the spleen may have, therefore, something to do with the elaboration of insulin would be indicated by the fact that the islands of Langerhans are three times as numerous at the splenic extremity of the pancreas as in other parts, and, further, at the terminal portion of the descending arm, where there is no communication with the splenic vein, there are no islets. The author is sure that the splenic vein serves as "a channel for the transmission of pancreatic and splenic ferments of the liver. Trypsin becomes a constituent of the entire blood stream where albuminoids are broken down into simpler bodies."

There are many causes for the enlargement of the spleen. Osler has given us an exhaustive list of the causes of splenomegaly. This is perhaps worthy of repetition at this time. It serves to show the great number of conditions varying from some of the metabolic disturbances in childhood to violent infections which have to do with splenic disturbance. It is as follows:

I. In children: (a) Disturbances of metabolism, rickets, amyloid disease; (b) Chronic intestinal affections; (c) Large but ill-defined groups of intestinal disorders, particularly in the tropics; (d) The pseudo-leukemia infantum (Von Jaksch's disease).

II. In the infections: (a) Syphilis; (b) Malaria; (c) Kala-azar and other forms of tropical splenomegaly; (d) Hodgkin's disease; (e) Tuberculosis.

III. In primary disorders of the blood-forming organs: (a) Leukemia; (b) Pernicious anemia; (c) Chlorosis; (d) Hemachromatosis; (e) Polycythemic splenomegaly.

IV. In cirrhosis of the liver: (a) Syphilitic; (b) Alcoholic; (c) Hypertrophic of Hanot.

V. Hereditary and family forms of splenomegaly: (a) Congenital acholuric icterus; (b) Constitutional disturbances, dwarfing, etc.

VI. New growths and parasites: (a) Sarcoma; (b) Primitive endothelioma of Gaucher; (c) Echinococcus; (d) Schistosoma of Japan.

VII. Splenomegaly not correlated with any of the above or with any known cause: (a) Banti's disease in its three stages: 1. Simple enlargement; 2. Splenomegaly with ane-

mia; 3. Splenomegaly with anemia, jaundice, and ascites.

European writers have given us quite a large number of reports of the findings in animals either splenectomized or treated with splenic solution. Some of these writers, as, for instance, Bayle of Cannes, is certain that the splenic function has to do with the development of antibodies and immunity. This investigator treated a large number of tuberculous cases with a splenic preparation, and, in his first paper, read at Rome before The Congress of Tuberculosis, in 1912, he says: "I feel authorized by my results to call splenic opotherapy a specific treatment for tuberculosis. . . . From the therapeutic standpoint, it modifies the soil, rendering it less suitable for the growth of the bacillus of Koch." This statement is very sweeping, and it is not our purpose to comment on it here. We are giving this report purely to show the belief this physician has in the function of the spleen. Quoting further from this author, we find: "Employed in convalescence, it prevents tuberculosis by increasing the mineral content of the tissue." He even makes more definite statements than this, and his belief that splenic solution or extract has a certain control of tuberculosis is one the writers could accept only after greater personal experience with this form of therapy. More of this later, however.

Hans Sollberger tells us that, after splenectomy in normal rabbits, there is an increase in the hemoglobin figures and also in the number of the red blood corpuscles, perhaps due to the reduction of hemolysis which must take place if we are to accept the original theory of the "graveyard" possibilities in the splenic reservoir. Sollberger believes that, after splenectomy, the bone marrow is more sensitive and has a greater working capacity, perhaps due to the removal of one party in a balanced action, the idea being that there is a mild antagonism, or ratio, at least, between the blood-destroying spleen and the blood-forming bone marrow. To prove this latter-mentioned theory, he injected hydrogen cyanide subcutaneously in normal and splenectomized animals. We know that the action of this powerful poison is hemolytic to a marked extent. Just why he chose this particular drug, we do not know, but, at any rate, it gave immediate depression in the amount of red blood corpuscles and hemoglobin in all animals treated. The normal animals were very slow in securing their former hemoglobin and red blood corpuscle figures, whereas the splenectomized animals, with readily active bone marrow, produced blood corpuscles rapidly and arrived at normal figures as to blood content much more readily than their normal fellows. Sollberger is confident that the ready increase in hemoglobin and red blood corpuscles is due to the rise in the efficiency of the marrow of the splenectomized animal. This same investigator removed the thyroids in rabbits to find, if possible, a compensatory change on the part of the spleen. He does not report any change in size or texture of the latter gland, but says that there is probably a non-specific stimulation of blood-forming organs, for he noted an increase in the formation of hemoglobin after thyroidectomy. These are interesting findings, but again of a purely academic type. We must remember, however, that the position of small straws

can readily indicate the direction in which the wind is blowing. To many, this idea of a balance between the spleen and bone marrow is new, and, while theoretical, is still sensible and worthy of consideration in certain diseased conditions. The ready relief in Banti's disease, in any stage, following splenectomy is a vindication of this idea.

Schröder, Kaufman, and Kögel have tested spleen pulp as a direct media for implantation of tuberculous cultures, and report that virulent tuberculous bacilli are weakened at the normal breeding temperature in such a media, and many of them are destroyed. Complete destruction or solution of the tuberculous bacilli was not noticed. The anti-tuberculous value of the spleen must be rather worth considering, for we know, not only from the findings of these investigators, but from the generally accepted principles in our own United States that the body of an animal is considered to be saturated with tuberculosis only when the spleen itself is thoroughly involved. In other words, when we have marked splenic tuberculosis, we have an organism whose resistance has been completely overcome in regard to Koch's bacillus, and that is why inspectors in our slaughterhouses throughout the country investigate the spleen in all cases first. The anti-tuberculous action of the spleen and its secretion is one that has aroused the attention of a large number of investigators other than those just mentioned—a function that we believe is worthy of further investigation, particularly after some experiences we have had in the last year or so. The proof of the value of splenic therapy is to be found, we believe, in clinical and animal experimentation rather than in vitro. In animals treated with splenic extract, there is a change that is readily observed and apparently consistent throughout the numerous resultful experiments.

Walter Frey and Erich Hagemann have brought forth a clinical test, which we believe is fairly delicate, to determine the functional capacity of the spleen. The test consists in injecting from 0.6-1 mg. of adrenalin subcutaneously and then counting the number of lymphocytes twenty minutes after the injection of the adrenalin. In cases who have a diseased or hypofunctioning spleen, the lymphocyte increase will be less than 1500 cells within the twenty-minute time limit. The results of this test cannot be considered absolute, but should be taken along with the general findings in the case. These two writers reported a series of sixteen patients tested with the adrenalin-lymphocytosis procedure and found only one doubtful result. In all the remaining fifteen cases, the reaction was accurately diagnostic of the true splenic condition: i. e., the positive reactions were present in those patients who had a normal spleen and the negative reactions in all instances were attended by a diseased spleen. We do not believe that this test is being used to any great extent in the United States, and we deem it worth while to consider it in cases in which we would like to know whether or not the spleen is diseased for obvious reasons.

From the Italian sector we have some recent reports from T. Silvestri, in which he reviews, as a result of his own experiments, some of the actions of the spleen, and also tells us of some of the origi-

nal digestive experiments which he is confident show a relation between splenic function and pancreatic secretion. In this review he tells us that the function of the spleen is partly to furnish the peptic glands with material of great importance to their normal functioning, although this particular substance is not indispensable, for pepsin is readily formed after a period of readjustment in splenectomized animals. He believes, however, that gastric digestion is never as active after splenectomy as before. In other words, there is a constant hypopepsia, but the other principles of the gastric juice remain unchanged. He tells us that the gastric ferments can be corrected quite readily by splenic organotherapy. The translator does not tell us, in the article which we have at hand, whether or not the splenic extract was given by hypodermic or by mouth. We should like to know more about the method of administration. The general principles involved, however, are interesting and worth recording here.

We are told further in this report from Silvestri that the three enzymes found in the internal secretion of the pancreas are unaltered by splenectomy. He states, however, that albuminoids are not digested by the pancreas after splenectomy, but the powers of the gastric juice, so far as the splitting of albuminoids are concerned, is markedly increased under the same conditions; and, further, we are told that this increase may become very great, perhaps making up for the simultaneous loss of that function on the part of the pancreas. This would lead us to believe that there is some relation between the pancreas and the spleen. As we have already stated, there is a circulatory arrangement between the two glands which definitely controls the location of the Langerhansian isles, for the portion of the pancreas, which extends beyond the spleen and is not connected with it in a circulatory way, has none of these specialized islets.

After looking over the previous discussion, many of us will be willing to agree with William Osler, who said that he enjoyed reading an article concerning the splenic function which contradicted a previous article on the same subject, for he had never been able to assure himself that the spleen had a definite business in life. Yet, we must not say that the work that has been done in this field was inaccurate or done in a slipshod manner. The rather elusive function of the spleen has aroused the interest of many men whose time could well be spent in research work, and they have contributed here and there some ideas that, while at first appearance may be antagonistic in the final expression of fact, yet we believe are capable of being correlated under proper headings; at least, we wish to make an attempt to do so, in view of the very definite findings that we have had in our experiments with splenic solution, and in which we considered an entirely new phase of action.

We believe that this attempt is worth while, for we find, as an expression of the common belief in splenic unimportance, the following paragraph taken from an editorial appearing in *The Journal of The American Medical Association*, January 7, 1922:

"Taken all together, an enormous amount of experimental work, as well as not a little careful clinical

study, has failed to show conclusively that the spleen is an organ of internal secretion, or to account in any way for the fact that it is a large organ, universally distributed in the animal kingdom, provided with a blood supply so large as to suggest that it must have great activity and most important functions. Whatever it does in the way of destroying decrepit red cells can be done elsewhere. Surely it must have some further task than this; yet, if it has, this must be readily carried on in other tissues, since splenectomy is so well endured; probably this is why we cannot find out just what the chief function of the spleen may be."

The material thus far placed in paragraph form for the reader's interest has been by way of preparation, so to speak, for our original work. We had originally begun our work with splenic extracts to test their action in cases of tuberculosis. This was due to the belief we had in their possibilities in this type of infection, not so much from personal experience as from observing the writings of others, and also from some discussions we had had with physicians who were beginning to become enthusiastic about this particular endocrine, if endocrine it is. Purely by accident, Miss Ablahadian discovered that the rabbits who had received intravenous splenic extracts were showing some phenomenal increases in blood calcium. The blood calcium tests were being performed at the time to produce, if possible, a briefer clinical method for determining blood calcium—a matter that had been brought to the attention of the medical profession by the work of Drs. Vines and Grove, of Cambridge University, England, who had been working with parathyroid extracts. So sharp was the increase of blood calcium in the animals receiving splenic extract, that a series of them were immediately placed upon this solution, the blood being tested at regular intervals for its calcium content. We were soon very much surprised to find that all of the rabbits placed on splenic treatment were found to have an increase in blood calcium; in fact, this increase was found to be several times greater than in rabbits who received parathyroid nucleoprotein by vein. We shall proceed, then, to give you some of the information that we have gathered during the last nine months after exhaustive experimentation and accurate laboratory work.

It is evident that an injection of spleen nucleoprotein causes the outpouring of a shower of ionic calcium in the blood stream. This increase in blood calcium is fairly rapid and reaches its greatest height in about twenty-four hours after the injection. In from twelve to fourteen hours more, the findings are, in terms of calcium, again practically normal, never becoming subnormal. It is evident from our findings that any excess of lime in the blood is shortly eliminated by the kidneys, and that is our main idea in adding a small amount of parathyroid substance to the splenic solution, since the parathyroid preparation evidently acts as a mordant to hold the excess calcium in the blood and to prevent its rapid elimination. We can readily see that the actions of splenic substance and that of parathyroid substance are, while similar in many ways, very different when it comes to the elimination of calcium. By combining the two preparations, we have a re-

markable stimulant to the chemistry of blood calcium and a hormone whose activity already has been demonstrated as being a conservator of blood calcium.

The following tables will show that the calcium is markedly increased after the injection of spleen solutions intravenously. In several instances as great a change as three milligrams was observed after the injection of splenic hormones, and in almost no instance have we observed a decrease in blood calcium. It seems that the reaction is very dependable:

Rabbit No.	Normal Calcium	Calcium after 2 injections	Calcium after 5 injections
4	14.40	15.42†	
4	14.78		15.00†
5	14.41		14.93†
6	15.9	15.80†	
6	14.43		18.20†
7	16.9	16.20†	
9	15.3	16.0*	15.6*
10	16.5	20.0*	17.4*
11	15.0	18.5*	15.2*
12	16.0	17.0*	22.1*
13	15.0	16.0*	19.6*
14	16.0	15.5*	21.0*

* Figure produced by spleen injections, 1 cc. daily.
† Figure produced by injections of a combination of splenic and parathyroid extracts, 1 cc. daily.

Blood-cell increases have been observed after the injection of spleen nucleoprotein. Contrary to the old belief that the spleen has a hemolytic action, it was found that the red blood-cells increased in some instances over one-half million in a few days' time and, further, that the blood hemoglobin was increased, as would be expected when the red blood-cells were augmented in numbers.

The clotting time was shortened markedly in every case. This was noticed very readily when drawing blood from experimental animals. In some instances, the blood clotted so readily that it was withdrawn from the marginal ear vein with considerable difficulty, the wound having to be freshened frequently.

Two rabbits were splenectomized and their blood tested at intervals for its calcium content. In both rabbits thus treated, the blood calcium dropped almost 50 per cent. A control animal was cut open and sewed up without tampering with the spleen or any of the other abdominal viscera. In this rabbit no change was noted in the blood calcium. The two splenectomized rabbits were given intravenous injections of spleen solution, after which the blood calcium came to normal.

In keeping with the foregoing considerations, a series of tuberculous patients was placed on splenic extract therapy (by hypodermic administration) with some satisfactory changes in the blood calcium findings. These patients thus far have been observed for a period of a little over one month. The clinical findings have not been changed markedly. The physical findings will probably respond more slowly to treatment in tuberculosis than in any other condition on account of the marked chronicity of the infection and the usual long periods of toxemia preceding the tests.

Further experiments must be carried out in tuberculosis to find, if possible, a strength of solution that can be used which will be comparable to the severity of the symptoms of the disease. Ordinary strengths of splenic extract are probably not sufficiently active for Koch's infection. Ordinarily, a 4 or 5 per cent

solution has been used. If we can double that in this condition, well and good. That particular problem remains to be solved.

We believe one of the possibilities of treatment with this solution lies in inhibiting a tendency to hemorrhage in pulmonary tuberculosis, as injections of solutions of spleen shorten the clotting time in a few hours after the injection.

It is evident that spleen solutions, when injected into the human economy, cause an outflowing of calcium which is constant, marked, and readily produced. Further, it is evident that this rapid increase of calcium will be followed shortly by a loss of that particular substance due to elimination and lack of a supply. Since parathyroid is capable of fixing the blood calcium and of preventing its undue elimination, a combination of parathyroid (the calcium conservator) and spleen will be an ideal one for use in all calciprivic states, including tuberculosis.

May we call your attention to the fact, then, that there is just one finding in common in all the list of conditions that are known to have splenic hypertrophy, or splenomegaly, so-called? If we look down through the list of diseases given by Osler, we can, at least, say that there is one thing in common in all of those disturbances, and that is calciprivia, demineralization, or acidosis, depending upon the reader's personal choice of a term indicating lack of alkali reserve, and, therefore, a need for calcium ions. The spleen may have something to do with hemolysis; it may have something to do with the elaboration of uric acid; it possibly is an important lymphatic gland, but, above all these functions, we wish to place its action as a calcium metabolism stimulant, preparing suitable calcium salts for presentation to the blood stream and the impoverished body cells.

KIDNEY ANOMALIES: REPORT OF A CASE OF BILATERAL FUSION OF A SUPERNUMERARY KIDNEY

By WILLIAM E. STEVENS, M. D., San Francisco

Examination of available literature fails to reveal a previously published case.

Bilateral fusion and horseshoe kidneys not the same in etiology or pathology.

If one chooses to classify the reported case as horseshoe kidney, it is still unique.

DISCUSSION by Louis Clive Jacobs, San Francisco; Burnett W. Wright, Los Angeles; A. S. Musante, San Francisco; E. Spence De Puy, Oakland.

Doctor Stevens supplies, with his interesting article, a complete bibliography of previous publications on the anomalies of kidneys. Under the policies of CALIFORNIA AND WESTERN MEDICINE, and most other general medical journals, bibliographies are not published. Workers interested in studying the subject more fully will gladly be supplied with a copy of the bibliography by the secretary of the California Medical Association or by Doctor Stevens.

I wish to utilize this opportunity to again call the attention of readers to the great assistance of the Cumulative Index of all worth-while medical literature published quarterly by the American Medical Association and furnished at a nominal subscription price.—EDITOR.

S anomalies of the kidney are more frequently encountered than those of any other organ, these conditions are of special interest to the urologist, and the possibility of their occurrence should always be considered in the presence of obscure lesions of the abdomen or upper urinary tract.

In 4215 consecutive autopsies, Lowsley, Kingery, and Clarke found 1.47 per cent of renal anomalies. In the records of 11,168 autopsies, Morris found abnormalities of the kidney in 211 subjects, a little less than 2 per cent. This author collected from the literature between 1883 and 1893, 21 cases of various malformations. Of these, 8 were horseshoe kidneys, 11 single, and 2 unilateral fused kidneys. Dorland, in 1911, collected 121 cases of renal anomalies which had been reported in the literature during the preceding twelve years. He added two of his own. Of these, 36 or 29.2 per cent were horseshoe kidneys, 24 or 19.5 per cent were single kidneys, 14 or 11.2 per cent unilateral fused kidneys, and only 5 or 4 per cent supernumerary kidneys. Eight of the third group were classified by Dorland as sigmoid kidneys, and six as disc-shaped kidneys. The former are now usually included with unilateral fused kidneys. Of these 123 cases, the sex was stated in 66; 53.2 per cent of the 123 occurred in males, and only 28 per cent in females. The left kidney was affected in a little over 70 per cent. In 1905, Gerard, quoted by Dorland, studied 527 cases of renal anomalies. He arrived at practically the same conclusions.

Considered from a standpoint of variation in number and form, these anomalies are, therefore, in the order of their frequency, horseshoe kidney, single or solitary kidney, unilateral fused kidney, and supernumerary kidney. Atrophic, displaced or ectopic kidneys and reduplication of the pelves and

Conference Board of Physicians in Industry—At a recent meeting of this interesting organization, it was agreed that many trifling injuries created no disability and required no redressing, but that many serious infections, entailing much loss of time and production, arose from the neglect of such patients. . . . Over 2000 infection cases were reported among 32,500 workers during 1924, and of this number only about twenty had received treatment prior to the appearance of the infection. It was thus seen that where prompt medical attention is given to injuries, infections are practically eliminated, and that practically all infections in such injuries result from delay in reporting for treatment. In the experience of the members of the conference the most beneficial results to the worker who is recovering from an injury are obtained in cases WHERE HE IS RETURNED TO EMPLOYMENT PENDING COMPLETE RECOVERY. Certain types of workers are unfavorably influenced by prolonged periods of idleness pending complete recovery, and it is hard to get such persons to again take up their usual employment. It was the unanimous conclusion of the board that the practice of permitting the worker to unduly prolong his idleness was a factor in delayed recovery and the development of traumatic neurosis and certain cases of malingering. In many patients a certain amount of physio-therapeutic treatment is necessary before any work can be attempted, but the board believes that supervised active motion of the previously injured part, carried out as work in the factory, also leads to more prompt recovery.

ureters, which are comparatively common, will not be discussed.

The feature of greatest interest, as well as the one of most clinical importance, is that of pre-operative diagnosis. An attempt will be made in this paper to correlate in as concise a manner as possible the symptoms of the above four types of renal abnormalities and to differentiate them from pathologic conditions of the upper urinary tract and abdominal organs.

As all types of renal malformations are frequently associated with abnormalities of other organs of the body, especially those of the genital tract, the presence of developmental irregularities of the latter organs should suggest the possibility of kidney anomalies. Abnormal organs are also more susceptible to disease and, as a rule, unless accidentally discovered, the symptoms of these complications first attract attention to the urinary tract. The most common pathological processes found with these conditions are hydronephrosis and calculi, although tuberculosis, pyonephrosis, and pyelonephritis are not infrequently seen.

HORSESHOE KIDNEY

Morris found 19 horseshoe kidneys in 18,244 recorded autopsies, Premdlberger, 6 in 1344 autopsies; Socin, 5 in 1630; Stewart and Lodge, 14 in 6500; Botez, 72 in 51,504; Carlier and Gerard, 80 in 68,000; Oleson 1 in 507; and Lowsley, Kingery, and Clarke, 1 in 600 consecutive autopsies. Summarizing, this anomaly was found once in 740 post-mortem examinations.

Braasch stated that, in 1000 kidney operations performed at the Mayo Clinic from 1910 to 1920, 17 were on horseshoe kidneys. They occurred more frequently in women. Botez stated that, in 1000 kidney operations, the proportion of horseshoe kidneys was 1-143, about two and one-half times as many as at the Mayo Clinic.

When subjective symptoms are present, the most common is more or less pain in the umbilical region. This is usually increased by exercise and relieved by rest in bed. Pain is also present in the lumbar region at times. Instead of definite pain, these patients sometimes complain of an uncomfortable feeling or sensation of pressure in the upper abdomen. Manipulation of the kidney frequently causes a peculiar, disagreeable, sickly, faint sensation along the thigh or in the hypogastric region. There may be periods of frequent or painful micturition brought on by muscular effort, by manipulation of the tumor or by pressure upon it by hardened or retained feces. Rovsing described three cases in which pain was evidently caused by pressure on the nerve trunks. Hickling described a case in which acute congestion of the fused kidneys caused compression of the inferior vena cava resulting in thrombosis of the vein and death from complete arrest of the circulation. A case has been mentioned in which pressure of the isthmus was responsible for aneurysm in the first part of the abdominal aorta.

In exceptional instances it is possible to palpate as a smooth oval mass the isthmus or bridge between the two halves of a horseshoe kidney, but in the majority of cases pyelography is of greater value in

the diagnosis of this condition. By the latter procedure, several anatomic features which are strongly suggestive of horseshoe kidney are demonstrated. These are: overlapping of the calices because of the antero-posterior direction of the pelvis due to the incomplete rotation of the kidneys which occurs in these cases, the closer approximation of the two pelves as a consequence of which they lie nearer to the median line, the anterior and slightly upward direction of the hilum and the high insertion of the ureter with a sharp, ureteropelvic angle. The importance of the injection of the media used for pyelography through a catheter which is introduced but a short distance into the ureter is worthy of emphasis. By this procedure the presence of one or more additional pelves or ureters will be demonstrated, and its value in that type of anomaly in which the ureters unite before reaching the bladder is obvious.

Byron Robinson, in a study of sixty specimens of horseshoe kidneys observed that 93 per cent possessed bilateral ureteral unicity, $3\frac{1}{2}$ per cent bilateral ureteral duplicity, and $3\frac{1}{2}$ per cent central ureteral unicity. No case of unilateral ureteral duplicity was found.

Fusion of two kidneys is always accompanied by some displacement, and palpation or ordinary radiography will disclose the fact that they are situated at a lower level in the abdomen. A mass in the upper abdomen, deformity of the renal pelvis, and an abnormality in the course or number of the ureters, is almost pathognomonic of this anomaly. In the diagnosis of horseshoe kidney, the presence of abnormalities of the genital and other urinary organs with which it is frequently associated should also be remembered.

DIFFERENTIAL DIAGNOSIS

A horseshoe kidney is to be differentiated from several pathological conditions of the abdominal cavity, the most common of which are tumors of the pancreas, tumors of the intestines, tumors of the omentum, tumors of the retroperitoneal connective tissue and inflammatory exudates.

Tumors of the pancreas are usually cysts or carcinomata. Pancreatic cysts are often associated with a history of trauma followed after a brief period by the development of a tumor in the upper abdomen. Others not associated with injury begin with severe pain which is followed by the development of a tumor. A third group develops more slowly, and is frequently associated with chronic inflammatory conditions of the pancreas. The tumor is palpable as a smooth globular mass between the ensiform cartilage and the umbilicus. It usually lays between the stomach and the transverse colon, but may be above or below them. Pancreatic cysts are most often found in the median line, otherwise more commonly to the left than to the right. Primary carcinoma of the pancreas is infrequent. Jaundice is common. The tumor is usually situated in the median line, occasionally on the left and rarely on the right side. It is usually dense, often nodular, and it is immovable. Dull pain and digestive disorders are frequent.

The majority of intestinal tumors are in the sigmoid, rectum, or cecum. If the tumor, which is

usually a carcinoma, is high in the intestine, obstruction is frequently present, and blood is found in the stools. These growths are more or less mobile at first. Inflation or bismuth enemata usually localize the tumor. Duodenal tumors give rise to pain in the right hypochondrium. There may be vomiting of bile and pancreatic fluid or jaundice. Unlike carcinoma, a horseshoe kidney is usually smooth and regular in outline. Solid or cystic tumors of the omentum are usually mobile and are not painful. Lipomata and sarcomata occasionally develop from retroperitoneal connective tissue. They are immobile and dense in character. Inflammatory exudates are usually accompanied by general disturbances.

SINGLE OR SOLITARY KIDNEY

Morris found in Gray's Hospital reports 1 single kidney in 4632 autopsies, in Middlesex Hospital reports 2 in 6536 autopsies, in St. Bartholomew's reports none in 3800, and in the autopsy reports of

Fig. 1.—Pyelogram of right kidney, showing overlapping of calices.

the Hospital for Sick Children 1 in 936. Peterson found 1 in 1500 autopsies, Sangali 3 in 5348, Menzies 2 in 1790 autopsies. Lowsley, Kingery, and Clarke found congenital absence of the kidney twice in their 4215 consecutive autopsies. Summarizing the above reports, we find that a single kidney has been found once in about 1259 autopsies. They occur somewhat less frequently than this, as some of the reports include atrophic and rudimentary kidneys. At the Mayo Clinic a solitary kidney was found once in every 142 kidney operations. They occur almost twice as frequently in males, and more often on the left side. There is a marked tendency to pathologic changes in single kidneys. Nephritis, calculi, tuberculosis, hydronephrosis, and pyonephrosis in the order mentioned have been most frequently found.

DIAGNOSIS

Ordinary radiography will reveal the absence of a kidney shadow on one side, and in the majority of instances a single ureteral orifice will be found on cystoscopy. While the frequency and volume of the ureteral spurt is usually greater in congenital single kidney, and increased kidney function is also suggestive, it is important to remember that the ureters from normal kidneys occasionally join before reaching the bladder. On the other hand, the presence of two ureters, both of which discharge urine, does not necessarily indicate that there are two kidneys. Pyelography or insistence upon repeated radiography until the kidney shadows are visible or the absence or displacement of one kidney satisfactorily proven is necessary in excluding a single kidney. While all of the above procedures are of importance, pyeloureterography is of greater value in the diagnosis of solitary kidney, as well as in all other abnormalities of the urinary tract. The number and course of the ureters is readily seen, and anomalies of the pelves are demonstrated. In this connection, Braasch has called attention to the fact that the pelvis of the congenital single kidney is enlarged in proportion to the increase in renal parenchyma, but is otherwise normal in outline, whereas in the acquired solitary kidney the pelvis is of usual size. The indigocarmine test is often of value when catheterization of the ureter or ureters and pyeloureterography is impossible. Malformations of the genital organs are more frequently associated with single kidneys than with unilateral fused or horseshoe kidneys, as in the latter anomalies fusion occurs after differentiation of the urinary and genital system has taken place in the embryo.

UNILATERAL FUSED KIDNEY

Morris found but one unilateral fused kidney in the autopsy records of 12,104 cases. Stewart and Lodge found one unilateral fused kidney in 6500 autopsies. Of 57 cases collected by Stein up to 1911, in which the sex was mentioned, 16 occurred in females, and 41 in males. In a study of the autopsy records, however, the fact that a greater number of males than females are available for this purpose is to be taken into consideration.

SYMPTOMS

The most common subjective symptoms of unilateral fused kidney are bearing down pain in the side of the abdomen, and constipation. If the kidney is situated at the pelvic brim, pain in the back and lower abdomen in women, most pronounced during menstruation, is often present. Vesical disturbances are not infrequent. An elongated kidney on one side can sometimes be palpated in the presence of this condition, and radiography shows the kidney at a lower level. Obstruction to the ureteral catheter will also be found at the latter point. Following distension of both pelves, pain will be felt on the same side. Pyeloureterography, however, is the only certain method of diagnosing unilateral fused kidneys. This procedure will demonstrate the unilateral position of both pelves, and will also reveal the abnormal course of the ureters. Stereoscopic pictures, following inflation of the colon or bismuth enemata, will serve to

demonstrate the retroperitoneal location of the mass, as well as the absence of intestinal involvement.

A unilateral fused kidney may be differentiated from carcinoma of the intestines by the absence of blood in the stools and by its smooth, regular outline. It is usually fixed, consequently it cannot be moved upward like a simple floating kidney or a movable liver or spleen. Following exposure, an unilateral fused kidney is easily recognized by its form and size and the direction of one ureter toward the opposite side of the bladder.

SUPERNUMERARY KIDNEYS

Supernumerary kidney is the rarest of renal anomalies. In a series of 24 cases, 23 of which have appeared in the literature and to which my own case has been added, 15 were on the left side, 7 on the right side, and but 2 in the midline. The sex was mentioned in 21 cases, 11 were found in females, and 10 in males. Two supernumerary kidneys are evidently extremely rare. Although Voigtel, in 1805, mentioned eleven or twelve writers who reported the presence of four kidneys, the only references to this condition since that time were cases reported by Monquoit and Oleson. The former found a kidney from seven to eight inches long placed transversely across the lumbar vertebrae, which had four pelves, ureters, arteries, and veins. In Oleson's case, the organ lay with the two extremities in the usual situation of the kidneys. The lower margins of what should have been the normal kidneys were continuous, with no apparent break in their structure. Two adventitious kidneys existed, turned with their hila directed obliquely outward and downward and their inferior margins continuing across the front of the aortic bifurcation. Each of these four kidneys was anatomically, and apparently functionally, perfect, with pelvis, ureter, artery and veins only differing from normal kidneys in fusing imperceptibly into each other.

Since the United States Marine Hospital report of a case of supernumerary kidney in 1885, other cases have been reported by Hyrtl, Wedensky, Mills, Israel, Gottfried, Depage, Hansemann, Rustschinski, Calabrese, Isaya, Tonkou, Cadenat, McArthur, Gavard, Monquoit, Oleson, Cheyne, Wilcox, Kretschmer, Samuels, Kern and Sachs, Newman and Barlette. In Kretschmer's case the supernumerary kidney contained thirteen stones. It was found on the left side in a woman 27 years of age. It lay beneath the left kidney, and had its own blood supply and a ureter which united with that of the left kidney. The latter was also full of stones. Samuels, Kern and Sachs reported a case of supernumerary kidney, the ureter of which opened into the vagina. The organ was situated on the right side. Gavard reported a case in which a supernumerary kidney was imbedded transversely in front of the lumbar spine. This central kidney had its own ureter, which joined that of the right kidney. Wilcox reported a case in which the three fused kidney elements were represented by an irregular, nodule mass in the midline at the level of the brim of the pelvis. Three separate pelves which fused into one huge, dilated pelvis were present. Newman mentioned a case in which a pear-shaped supernu-

merary kidney was situated close to the upper margin of the left kidney. Cheyne reported a case in which the patient suffered from definite abdominal pains, indigestion, and a general hysterical condition. When the pain was severe, there was a diminution in the quantity of urine passed. He thought that the symptoms were due to mobility of the kidney, with slight pressure on or kinking of the ureter.

CASE REPORT

My patient, a married woman 23 years of age, complained of chronic constipation, backache, most pronounced in the lower lumbar region, general weakness and a "tired feeling" on exertion. She had suffered from constipation, which was severe enough to require a laxative every other night, for three years. The other symptoms were of one year's duration. The backache was relieved by rest in bed. It was worse during the menstrual period. The latter was accompanied by severe cramps in the lower abdomen. Six weeks before entering the hospital she had remained in bed for three weeks. After getting up she flowed for two weeks, the last three days of which she spent in bed. Abdominal examination was negative except for the presence of a firm, smooth, oval mass about the size of a large

hen's egg, a little to the right of the midline and just above the umbilicus. It was slightly movable and gave the impression that it might be connected with the right kidney. It was hardly sensitive to pressure, although manipulation occasionally caused sharp pain. Aortic pulsation, more forceful over the inner half of the mass, could be detected. The pelvic examination was negative. Examination of the gastro-intestinal tract was also negative. The urine was chemically and microscopically negative, and the patient had never complained of any urinary disturbances. Cystoscopic examination showed a normal bladder sphincter, mucosa, and ureteral orifices. The latter were readily catheterized to pelves which were but slightly displaced downward. Kidney function was slightly increased on the right side. A pyelogram of the right kidney pelvis revealed marked overlapping of the calices. An abnormality of the kidney or adjacent structures was then suspected, and an exploratory laparotomy deemed advisable.

The abdomen was opened through a right rectus incision, and the posterior peritoneum incised over the most prominent portion of the mass. A kidney with normal pelvis and ureter was then seen lying transversely across the lumbar vertebrae. The hilum was directed upward, and the ureter ascended about 1½ cm., then turned to the right, descending about 1 cm., where it fused with the right ureter. Palpation disclosed the fact that both poles of this

kidney fused imperceptibly with the lower poles of the right and left kidney, the entire structure thus resembling the horseshoe type of kidney. Further exploration revealed an appendix which showed evidence of previous inflammation and a cystic ovary. Both of these structures were removed. Following operation, the patient's symptoms were somewhat improved, but she still complains of pain in the hypogastric region, worse during menstruation.

There are no characteristic symptoms attributable to a supernumerary kidney. The condition is usually discovered following investigation because of some pathological condition with which it is associated, as like all anomalous organs they are more susceptible to disease. The presence of additional ureteral orifices in cases of supernumerary kidney is suggestive, but without pyeloureterography a positive diagnosis of supernumerary kidney is impossible.

Pyeloureterography, with the catheter just inside the right ureteral orifice, would probably have revealed the supernumerary pelvis and ureter in this case, but it has been impossible to gain the patient's consent to a repetition of this procedure. Pyeloureterography following the administration of sodium iodide by mouth failed to disclose these structures.

After a somewhat extensive search of the literature, I have been unable to find a single record of transverse fusion of three kidneys. This case differs from a horseshoe kidney, in the number and location of the ureters and in its position above the umbilicus. The right and left portions of an ordinary horseshoe kidney are lower than the normal position, and the inferior border of the isthmus is seldom higher than the sacral promontory. If one chooses to classify this case as a horseshoe kidney, it is still unique, as a careful review of the literature reveals no instance of a third ureter connected with the isthmus of a transversely fused kidney.

Flood Building.

DISCUSSION

LOUIS CLIVE JACOBS, M. D. (Flood Building, San Francisco)—Dr. Stevens' paper is of especial interest, as it emphasizes the prevalence of anomalies of the kidney. This is of great importance in the diagnosis of abdominal tumors, inasmuch as malformation of the kidney is usually associated with considerable nephritic displacement.

The clinical diagnosis of a bilateral fusion of a supernumerary kidney is practically impossible. A cystoscopic study, with the insertion of the opaque catheter and the introduction of fluid into the kidney pelvis, in conjunction with the roentgenogram, is the most practical way of determining kidney pathology, and in Dr. Stevens' case was of material value in the diagnosis of the kidney anomaly.

Malformations of the kidney have often been mistaken for malignant growths. Where it is absolutely necessary to elucidate a differential diagnosis, the procedure to employ is exploratory laparotomy. However, if in the investigation of a kidney tumor-mass one feels justified in treating the kidney surgically, he must first ascertain by direct catheterization and functional tests whether there is another healthy kidney present, independent of the mass.

Anomalies of the kidney are embryologically associated with anomalies of the ureter, and a complete physical examination usually reveals some abnormal embryonic development elsewhere, more often in the urogenital organs.

It is not infrequent with the better-trained cystoscopist to find a greater number of multiple ureteral orifices with two ureters running to a kidney, where formerly this was thought of as a very rare condition. And though there has been, as Dr. Stevens states, but twenty-three cases reported, I am sure there are a large number of other cases which were passed unrecognized, due to incomplete investigations.

BURNETT W. WRIGHT, M. D. (527 West Seventh Street, Los Angeles)—This very interesting and authoritative paper should attract new interest to kidney lesions, not alone from urologists, but from those men who do abdominal surgery. The frequency with which the abdominal cavity is opened for the relief of symptoms originating in the kidneys or ureters, behind the peritoneum, is well known, and in every case in which there is the least doubt, a careful cystoscopy and kidney study should be insisted on. Palpation of both kidneys and along the course of both ureters should be a part of every laparotomy in which there is any question of the cause of symptoms, and if this were done with the care with which the average surgeon investigates the appendix, the gall-bladder, the liver, the pancreas and the duodenum, while working within the abdominal cavity, many anomalies and displacements of the kidney that are being overlooked would be recognized.

Many anomalous and misplaced kidneys function perfectly during life and are not discovered, unless at autopsy or by palpation from within the abdomen during an abdominal section. One of the frequent ways by which they attract attention is by interfering with pregnancy. This is especially true of the misplaced kidney. The enlarging uterus, by pressing on the deformed or misplaced kidney, interferes with drainage and predisposes to retention and infection.

A. S. MUSANTE, M. D. (916 Kearny Street, San Francisco)—It is a pleasure to respond to the request for a discussion of this paper. Dr. Stevens is to be congratulated for having encountered a kidney condition which has all of the characteristics—relating to number, shape, and position—of these anomalies, instead of only the usual one or two, and has not before been recorded in medical annals, and deserves our praise for the studies and the investigations of the literature pursued in preparing his essay. The author's opening statement, "that anomalies of the kidney are more frequently encountered than those of any other organ," should be compared with Keyes' declaration: "Abnormalities of the kidney are very rare" (Urology, 1917).

The case itself is an example of the advantage of the abdominal approach to suspected kidney lesions. The only missing evidence was a pyelogram of the extra organ, which would probably have been obtained "with the catheter just inside of the ureteral opening." The remembrance of this case will impel us to carry out a more thorough survey of the kidney regions in abdominal surgery whenever possible.

E. SPENCE DE PUY, M. D. (Dalziel Building, Oakland)—Dr. Stevens is to be congratulated upon his rather extensive assemblage of references to kidney anomalies, and upon his careful consideration of the same. The question occurs to me, however, and apparently from the concluding sentence in his paper the same thought is in Dr. Stevens' own mind, that possibly the case he reports is not, after all, that of a supernumerary kidney.

Is it not more likely, and the embryology of kidney development would seem to bear out the idea, that the case under consideration is that of a fused horseshoe kidney with reduplication of the pelvis on the right side? This, though, is a question which may not be determined by an ante-mortem examination.

DOCTOR STEVENS (closing)—It is only within the last few years that the comparative frequency of kidney and ureteral abnormalities has been appreciated by the urologist. Their recognition is due to improved diagnostic technique and the increasing popularity of pyelography. A knowledge of the presence of these conditions is of obvious importance to the surgeon when operative procedures are contemplated.

A supernumerary fused kidney could have been produced in our case by the development of two closely approximated renal buds from one of the Wolffian ducts, the fusion occurring because of the close contact of these buds and union of their metanephric substance.

Any man that is faithful can overcome the disadvantages of a country practice, and if he cannot there is something radically wrong with him or with the community. He is entitled to good pay for good service.—Austin Flint (Iowa Medical Journal).

ESOPHAGEAL DIVERTICULA

By E. C. MOORE, M. D., Los Angeles

Diverticula of the esophagus are much more frequent than was formerly appreciated. They ought to be recognized more often and earlier in the course of the disease than they are.

The clinical picture, if formed from all the evidence, is clear and definite.

Good surgery is the treatment of election. The mortality has been much reduced by wider knowledge of what to do and how to do it.

DISCUSSION by George Thomason, Los Angeles; Charles D. Lockwood, Pasadena; and John Hunt Shepard, San Jose.

IN tracing the course of the esophagus, we recognize at its junction with the pharynx, in the median line posteriorly, a union of the oblique muscles of the pharynx and the transverse circular muscles of the esophagus, where there is a small area not covered with musculature, but only a subcutaneous layer. At this point, most of the diverticula occur, due probably to a more than ordinary weakness or a congenital absence of muscle-fiber, which, in the act of swallowing, permits a pushing out of the mucosa and submucosa through this small triangular defect.

The congenital nature of the disease has been based on the analogy to other diverticula of the gastro-intestinal tract; the improbability that the diverticulum on the posterior surface of the esophagus is caused by pull or pressure, because the spinal column offers a rigid background and would prevent any such factors from coming into play; the condition is completely developed when the symptoms first begin to appear. This may be demonstrated by x-ray examination and by gurgling sounds on swallowing, caused by the entrance of air and fluid into the previously existing space of the diverticulum; there are no manifestations in earlier life because the tissues are elastic, but the turgor is lost later in life (at 40), and symptoms may suddenly appear as a result of the condition which has existed for a long time, but has been dormant; and upon the fact that there is no recurrence after radical operation and the characteristic preference for the male.

In the weakened triangle (Lannier-Hackerman area) we find the pulsion or pressure type of diverticula. It is rare to find a true pressure type in any other part of the esophagus.

Traction diverticula may occur at any point, but usually are within the thoracic part of the esophagus and are caused by some previous irritation such as the cicatrix of a broken-down lymph gland or some other pathological condition of the mediastinum pulling on the esophagus. Zenker defines the traction type as one "in which the wall of the esophagus has been dragged outward by an external force."

Beverman found in sixty cases that 73 per cent were due to tubercular infection and other diseases of the lungs, and that pericarditis was responsible for the remainder.

This traction diverticulum is small and usually located at about the level of the bifurcation of the trachea. It is not met with so often as the pulsion and probably occurs under tension. While it may be congenital, it is not progressive. Occasionally, it is

incidentally found while passing the stomach tube or in x-raying the gastro-intestinal tract.

Ordinarily, we find diverticula of the esophagus considered under these two heads. Halstead classifies them as:

A. Pressure or pulsion which include:

1. Those of the pharynx.
2. Those of the pharyngo-esophageal junction.
3. Those originating near the bifurcation of trachea just above the left bronchus.
4. Those deep-seated, whose orifice is a little above the diaphragm, with the fundus of the sac resting on it.

B. Traction diverticula.

C. Traction-pulsion diverticula.

Treatment from a medical standpoint applies particularly to the traction type, and is directed to the primary lesion that is responsible for the production. If mucus or decomposing food is present, lavage is indicated. The patient is advised to avoid coarse food and alcohol. The pulsion type eventually becomes surgical. The larger may prove to be fatal as they increase in size, and as the amount which they can contain not only increases but becomes a source of danger and discomfort from decomposition of the contents, swallowing becomes more and more difficult until, in the extreme picture, the patient in his effort to swallow simply fills up the diverticulum, and little food, even liquid, passes into the esophagus, and unless relieved, starvation may result. Sometimes building up by feeding through a small stomach tube or catheter is necessary, or, in extreme cases, by a gastrostomy. The pouch fills from above; it is oval and the outline distinct. Its location is cervical, posterior or posterolateral in relation to the esophagus, and the diverticulum follows the movement of deglutition.

Percussion may suggest the diagnosis. The use of the catheter and sound may supplement this evidence. The method of guiding the sound by a silk cord, swallowed, and allowed to pass into the intestine until anchored there, is often resorted to. Radiologic examination is necessary.

It is possible to mistake the condition for a high spasm of the esophagus; also it may be interpreted as a dilatation above a constriction and not a sac lying along the esophagus. Different radiograms will promote distinguishing data. The ejection phenomenon is of diagnostic value; this consists of emptying the contents of the diverticulum into the esophagus on deglutition when no food is given. With the possible existence of a diverticulum being kept in mind, together with characteristic history and typical radiographic findings, its recognition often is easy without sounding or esophagoscopy.

The neck of the pulsion diverticula seems always to be small, but the pouch may be large enough to hold ten or more ounces. It gradually enlarges and develops a semi-inflammatory thickening of fibrous tissue, at first in mid-line growing down in front of the spine, then bulging to the sides, increasing usually more to the left. The large sacs grow into the mediastinum and become intra-thoracic; here they increase still more rapidly. Walls of the large

sacs are thinner than those of the small, less fused and easier to separate.

A diverticulum in the esophagus has the same effect as a foreign body which irritates the parts. Symptoms depend upon the size and position. There is a tendency to cough and other signs of irritation, on account of the proximity to the larynx. Clucking and gurgling sounds occur on speaking and swallowing. There may be a sudden explosive emptying of the pouch if the mouth is wide, and there is a strong muscular contraction. There is dryness of the pharynx, difficulty in swallowing, and regurgitation of food. At times food suddenly flows out of the nose when the patient bends over, pieces remaining wedged in the esophagus and not passing down. The patient is obliged to take but small quantities of food into the mouth at a time, swallow completely before taking more food, and may use various manœuvres of position and pressure to facilitate deglutition. There is excessive secretion of mucus, the breath is bad from decomposed food and constant indigestion. If the pouch is large and filled the patient complains of a lump in the throat. It may be so large as to cause serious respiratory symptoms with increased difficulty in swallowing, relieved by induced vomiting. Pain is not usual unless ulceration occurs.

Fully developed symptoms comprise obstruction, dysphagia, pain, regurgitation, especially when the body is prone or inclined forward. Fetid breath, congested face, cervical tumefaction, gurgling, compression signs, such as dyspnoea, neuralgia, and voice changes are frequent symptoms. The patient is usually nervous, irritable, and choleric. Occasionally, he presents only symptoms of psychosis, and only by exhaustive study is diverticulum discovered.

Medical treatment is often demanded, but is never fully satisfactory. It seeks to keep the pouch empty and overcomes stenosis.

In the pulsion type, surgery is indicated. Good results are obtained. Formerly, surgery was attended with great risk, and performed only to meet an emergency. Local anesthesia was used. The danger then lay in the way the sac was isolated and amputated. Many of them leaked into the raw tissues; sepsis and mediastinitis followed.

There are various methods for eliminating the sac. It can be drawn up by forceps and pushed down inside the esophagus, providing adhesions do not prevent. Other methods include external removal, change of position, and obliteration. The great danger is from leakage and infection, suffocation from the contents of the sac pressing with a subsequent broncho-pneumonia.

If a general anesthetic is used, the sac must be well emptied before attempting surgery, so as to prevent any chance of the contents pouring into the trachea, which would probably produce suffocation or cause a broncho-pneumonia.

Operations may be done in one or two stages. When the sac is small it matters little what method is chosen, but when large and intra-thoracic, the two-stage operation is advisable.

The incision usually recommended is parallel to the anterior border of the sternomastoid muscle. The collar incision is preferred by many. If one-

third of the mass is behind the anterior border of the sternum, and the skin and the platysma muscle is dissected both ways from this, there are few vessels to ligate. By blunt dissection and retractors, the sternomastoid and omohyoid muscles and the anterior jugular vein and common carotid artery are drawn back. Anteriorly, the sac is seen just behind and extending below the cricoid cartilage. The sac is light-colored and has a small plexus of veins over it. The large ones are drawn out with more difficulty, and much care is needed to keep from rupturing the sac. There is not much difficulty in amputating any of the sacs, and suturing at the junction with the esophagus. Two rows of chromic catgut and a small rubber drain are usually placed. Some elevate the sac and fix its fundus to the hyoid bone, to prevent infection, cellulitis, and fistula. Murphy delivered the sac unopened, then twisted it; later amputating, closing fistula and invaginating the sac by sutures.

Only a few hundred operations are on record. The mortality has been given as high. In a series of 200 cases there were reported 16 deaths; in 109, 12; and in 100, 10 deaths and 28 fistulas. Judd reports 3 deaths in 75 cases. The reported mortality of 16.6 per cent includes those cases operated on before rigorous asepsis was observed.

In selecting a method of operation, we want the one where there is least danger from infection, cellulitis, and fistula. I believe the most satisfactory method is where the sac is fixed to the skin incision and left unopened, with its neck ligated to slough out of the packed wound and be removed a few days later. Excellent results have been obtained with this procedure. Owing to the lack of time, I shall cite only my most recent operative case.

A man, age 63, in addition to an esophageal diverticulum, had cataract on each eye. He had seen an eye surgeon for the removal of the cataracts who, on examination, felt that the irritation of the patient's throat with cough and difficult swallowing would interfere with the success of the cataract surgery by breaking open the eye with ensuing disastrous results; therefore, the case was referred to me for treatment of the esophageal condition before further attention to the eyes. The patient had had trouble in swallowing his food for twenty-six years. Within a few minutes after eating, food would be regurgitated. The throat was much irritated, and it seemed as if there were a lump there. The initial symptoms followed diphtheria twenty-six years before, when he believed his throat to be partially paralyzed. The condition never disappeared and became progressively worse during the past eight years. In ten years he had lost thirty-five pounds, was very nervous and had had considerable sore throat, for which the tonsils had been removed.

Radiographs showed a diverticulum of the esophagus. The operation was performed under general anesthesia. The diverticulum was found to arise from the left side of the cricoid cartilage. It was 6 x 3 inches in size, and the neck was about half an inch in diameter. The operation consisted in dissecting and freeing the sac, bringing it out between the sterno-mastoid and sterno-thyroid muscles through a collar incision, with drainage into the sac.

On the sixth day the sloughing sac was amputated. The patient made a good convalescence and was out of the hospital on the eleventh day. A few weeks later the cataracts were removed.

These patients are not considered so rare as they were ten or fifteen years ago, nor as poor surgical risks. There is wider knowledge of the possibility of their existence and a better acquaintance with the typical syndrome they produce. If the patient is in good physical condition, little fear is warranted in making a favorable prognosis. If the patient has become emaciated from inability to swallow food, then we have the task of building him up by feeding, and getting him in fit condition of nourishment before operating. In extreme cases a gastrostomy may have to be done preceding treatment of the diverticulum.

A surgical technic that will prevent leakage and infection is the next step. This has been accomplished, as stated before, by bringing the sac through and attaching it to the skin incision; ligating and amputating later.

With the above points in view, it would seem possible to perform radical operation in these cases of esophageal diverticulum with a small mortality rate, and with ultimate good results.

Merchants National Bank Building.

DISCUSSION

GEORGE THOMASON, M. D. (Hollingsworth Building, Los Angeles)—Doctor Moore has covered the ground so thoroughly that there is little left to be said. I have had a number of these patients in the past few years. One sign which has not been mentioned is that of a change in the contour of the neck, especially, of course, in the larger and more fully developed diverticula. As the patient swallows and the diverticula fills, there is a marked bulging of the neck on that side. With the regurgitation of the food and the emptying of the diverticula, the neck promptly returns to its normal appearance.

The chief reason why the traction diverticula are practically never of surgical importance, is that the opening into the esophagus is usually the lowest part of the diverticula and, therefore, empties readily and does not tend to increase in size or embarrass the function of the esophagus.

So far as operation is concerned, my personal experience has been with the Sippey-Bevan operation of puckering the sac and folding it upon itself accordion-like, thus collapsing the diverticula and plugging the opening with the sac itself.

One fundamental feature for success in any type of operation is to either keep the sac entirely closed as in the Sippey-Bevan operation, or do the two-stage operation of the Jackson-Gaub-Judd type. The absence of any serous coat on the esophagus means almost certain failure so far as immediate closure is concerned, and to open the sac before adhesions have formed around the site of operation is to court disaster from acute mediastinitis.

CHARLES D. LOCKWOOD (Citizens' Bank Building, Pasadena)—I wish to report briefly a case of diverticulum of the esophagus upon which I operated over twenty years ago. I think it is one of the first cases in which the x-ray and an opaque solution were employed for diagnosis.

The patient was a woman about 50 years of age, with a very large diverticulum in the cervical region. An x-ray was first taken with a stomach tube in the esophagus, through which a copper wire had been passed. The tube could not be passed into the stomach, but coiled up in the sac of the diverticulum. Later pictures, with a bismuth mixture filling the sac, gave an excellent outline and revealed the size of the diverticulum.

The patient became so emaciated from regurgitation of food that a gastrostomy was done before attempting removal of the diverticulum. She gained thirty pounds in weight after gastrostomy. The sac was then exposed through the neck, and partially removed. It was so large

that complete removal was impossible. The remaining portion of the sac was plicated and its cavity greatly reduced. The patient remained well for several months and was able to swallow normally, but the diverticulum recurred and she finally died of starvation. In such extreme cases I believe gastrostomy is of great value.

JOHN HUNT SHEPARD, M. D. (San Jose)—A year ago, at our meeting in San Francisco, I read a paper before this Section on this same subject and reported two cases seen during the previous two years. Since then I have seen another case. I am confident that this condition is not as rare as we formerly considered it. These diverticula should be recognized before they attain a large size and seriously interfere with health. There is one point mentioned by Dr. Moore which I wish to emphasize, as I considered it the most important point in technique in all esophageal work. I refer to the use of the silk thread. With a little patience and perseverance it is possible to get the thread through any and every incomplete esophageal obstruction. Though at times it may be advisable to follow the thread with a linen fish-line, or even introduce over the thread a fine piano wire, once the silk is anchored in the intestine the continuance of the examination and treatment is rather easy. By the use of this technique, gastrostomy is practically never necessary. In all cases where caustics have been swallowed, the silk thread should be introduced before cicatricial contraction begins and kept in place until the degree of stenosis is determined. I agree with Dr. Moore that it is preferable to use a two-stage operation in all cases of large diverticula, but as these cases become recognized earlier, there will be fewer requiring the two-stage method.

ROENTGEN THERAPY OF UTERINE MYOMA DURING PREGNANCY

By JOHN D. LAWSON, M. D., Woodland, Calif.

(From the Department of Radiology, Woodland Clinic)

A review of the literature. Full report of one case. For literature reviewed, see Index Medicus or Cumulative Index, A. M. A.

Discussion of the value, indications and contra-indications of extensive roentgen treatment in the pregnant woman.

Pelvic irradiation of females who may become pregnant should be done with much care in selection of cases, and either only very light dosage employed or complete castration effected.

Pelvic irradiation of pregnant females should not be done except where there are very extenuating circumstances, and in any event the patient and her husband should be informed of the possibility, if not probability, of a deficient child.

Irradiation during the later months of pregnancy, if conclusions may be based on the results in six cases, is less injurious to the fetus than irradiation during the early months.

It would seem that the longer the elapse of time between irradiation and subsequent pregnancy, the greater is the probability of a normal child being born.

Radiography should be limited during pregnancy to the minimum.

Roentgen abortion or castration should never be performed except where there are definite reasons why the ordinary surgical procedures should not be followed.

There seems to be little difference between the actions of long and short waves on ova, either fertilized or unfertilized.

Additional evidence and opinions contained in the discussion by Francis B. Sheldon, Fresno; Kurt F. Behne, Los Angeles; Frederick H. Rodenbaugh, San Francisco.

THE selection of title was made hurriedly and unfortunately. Facts which should be brought out in reference to irradiation of the germ cells previous to fertilization, as well as other pelvic conditions treated during pregnancy by irradiation, are not included in the title, but I feel that it is best to

make the title a misnomer rather than to limit the scope of this paper conform to it.

Certain results observed by different men on irradiation of the male and female cells previous to their union have a direct bearing upon the result observed after irradiation following impregnation, and a consideration of one without the other would be incomplete.

The first work showing effect of irradiation upon fertilization of cells was probably done by F. Shaudinn in 1899, on protozoa. His article, however, did not cover the subject with any great accuracy, nor were his observations of any great value, except as a pioneer in the field.

Bohn, in 1903, described deformities and arrests in development of frog embryos resultant upon irradiation. His work was quite complete and well controlled, and is the first real scientific effort along this line.

Gilman and Baetjer, in the same year, reported results of experiments in which they irradiated the fertilized ova of amblystoma. They noted particularly that there was at first an apparent stimulation in growth of the embryo and then a depression. There always was a resultant deformity characteristically of the head and brain.

Much experimental work continued, especially under the observation of Hertwig and his school, who did extremely painstaking work, especially on the semen of frogs and the eggs of seagulls and various nematodes. This school verified the observation of Gilman and Baetjer, especially on the resultant skull and brain injury.

Baldwin working with frog ova in 1919, Bagg in 1920, and Little and Bagg in 1923, working with mice, noted deformities of the products of the irradiated ova.

Bagg, in his work, irradiated female mice previous to impregnation, shortly after fertilization, and during the latter portion of the pregnancy, and found similarity in the results obtained by the three methods. He used in his experimental work radium emanation in three ways: first, as a gamma ray pack; second, subcutaneous injection; third, intravenous injection. The results were comparable in all three methods, the deformities observed consisting chiefly of injury to the head and neopallium and numerous areas of subcutaneous extravasation. Abortion was frequent in these cases, especially when the irradiation was given during the early part of the pregnancy. There did not seem to be any difference in the end-result of the irradiation of the female before fertilization and irradiation during pregnancy. The most common deformities were noted in the brain and eyes. Blindness being a very prominent feature of all these experiments.

Little and Snyder, in 1923, continued the work of Little and Bagg, but their observations did not allow them to verify the latter's work.

From a clinical standpoint, probably no therapeutic pelvic irradiations were given during pregnancy until 1914. No observations were registered in the literature until 1920, when Ashenheim reported a case in which the patient was given five irradiations for myoma between the second and the sixth months of gestation. The fruit of the preg-

nancy was a male child delivered at eight months, underweight and underdeveloped, showing a definite microcephaly, aplasia of the right optic nerve, atrophy of the left optic nerve, neuroretinitis, strabismus, mystagmus, and imbecility. This child was followed through the age of 6 years, and was definitely slow in development. The irradiation in this case was evidently of the short wave type, as the treatments were one hour each and included both a posterior and anterior field of application, other factors used not being noted.

Stettner, in 1921, reported a case of treatment for myoma during the second month of pregnancy, with the resultant delivery at eight months of an underdeveloped child, weighing 1850 grams, showing hypospadias, strabismus, neuroretinitis, and definite mental changes. At 2 years of age the child could not speak. The dosage in this case was also probably of the deep therapy type, copper filtration being used, and the castration dose of Seitz and Wintz being administered.

Berkeley, in 1921, reported a case of treatment of carcinoma of the cervix in a pregnant woman, the irradiation being administered in the sixth month of gestation. The patient was delivered at term by hysterotomy, a normal viable child being obtained. The only abnormalities noted were two bald spots on the child's head, corresponding to the site of application of the radium. This child was followed to 7½ years without any defects being noted, the hair coming in shortly after birth. Radium was used in this case, and the dosage totaled 3712 mgh., evidently chiefly gamma rays being used.

Field, in 1922, administered heavy irradiation during the sixth month of pregnancy to a patient with carcinoma of the cervix. The fetus was delivered normally in the eighth month, was apparently normal in all respects, except that it weighed but four pounds (1.8 kg.) at birth. At the end of three and one-half years reports indicated it was a healthy child. The treatment in this case consisted of 7320 mgh. of radium, only gamma rays being utilized.

Bailey and Bagg report two cases of pelvic irradiation during pregnancy. The first had carcinoma of the cervix on which both bare emanation tubes and gamma pack were used in the sixth month of gestation, the patient being delivered by hysterotomy for eclampsia in the eighth month. The child weighed four and one-half pounds (2 kg.) and was apparently normal, but died in ten weeks of pneumonia.

The second patient referred to in this article had an epithelioma of the vulva and was treated with both bare tubes and gamma radiation in the fifth month of gestation. A normal child was delivered at term by hysterotomy and was living and well at time of report.

These are the only authentic records of therapeutic pelvic irradiation during pregnancy which I have been able to discover. There is, of course, the work of Archangelsky, who in 1923 reported a series of therapeutic abortions chiefly for pulmonary tuberculosis. Ten cases, the duration of pregnancy being from one and one-half to four months, were

treated. In seven of the cases abortion resulted. The remaining three were not successful within the time observed, although none of them was allowed sufficient time to obtain a definite result, operative interference being instituted in each case shortly after the last treatment. Three pregnancies were noted in the series after abortion, but the results of these pregnancies were not noted. The factors used by Archangelsky were as follows: 2 Ma., 55 Kv., 1 mm. al, distance and time not stated, but an average dosage of 45 H. was used, evidently bringing the irradiation under the classification of long-wave therapy.

Probably the most important feature of Archangelsky's series has not been included in his report, namely, the results of the three pregnancies following therapeutic abortion.

Considering now the influence of pelvic irradiation of the female not pregnant, but with a reasonable possibility or probability of future pregnancy, we have numerous articles referring to this subject, and while, as was stated at the beginning, the title itself is not sufficiently broad to cover this phase, nevertheless it appears to me that the consideration of this angle of irradiation cannot be divorced from that of treatment during the gestation period.

Stacy, in 1922, reviewed the cases handled at the Mayo Clinic, the total of which was 1113, in which pelvic irradiation for various conditions was employed in women of all ages. This, of necessity, would include a large number of cases where there was no possibility of future pregnancy; it also presumably included a certain number of cases in which definite follow-ups could probably not be obtained. However, in this series Stacy reports ten pregnancies, and of this ten, four of the children were normal, and at the time of writing were living and well. Three of the pregnancies resulted in a still-born fetus. Two of them miscarried, and one was pregnant at the time the article was written. This would give a percentage of, at the most, 50 per cent normal pregnancies. Stacy does not note after what type or amount of irradiation these pregnancies occurred, so that the influence of the amount and type of irradiation cannot be taken into consideration.

Werner, in review of his cases, 990 for essential metrorrhagia and 552 for myoma, notes that there were twenty-four pregnancies following irradiation; of these twenty-four, thirteen were carried to term with a normal labor and a normal living child as a product. One case was delivered normally about one month before term, the child being viable and normal. Nine cases aborted between the second and fifth months, three of these abortions being induced. One fetus was delivered by hysterectomy before term, the reason for the hysterectomy not being given. It is rather difficult to analyze Werner's statistics, as four of twenty-four cases were artificially terminated and the end product could not be, or was not, determined.

Clark and Keene, in 1922, reported a series of 527 cases of pelvic irradiation for various conditions, with seven pregnancies following irradiation. Out of these seven cases, only two were delivered at term of a normal child.

In Polak's series of treatment of menorrhagia in

young girls, two pregnancies have been noted, the end-result of these pregnancies not being stated.

Steiger reports one case of pregnancy following a two-year period of amenorrhea after irradiation, with delivery of a normal child.

Of much interest is the case of Bailey and Bagg in which irradiation, by radium pack of the intrascapular region for glioma of the cord was administered in the third month of pregnancy with hysterotomy at term, a viable child being delivered. However, the child had a spina bifida and a double club-foot, and died at the end of fifteen days. A second case in their report is one of Hodgkins' disease, in which irradiation was given during May and December, 1917. The areas irradiated were neck, groins, back and axilla. Pregnancy began at about the time of the last irradiation, and the patient was delivered in September, 1918. The child had a malformation of the head with the sagittal suture open, exposing the brain and died in eleven hours.

These writers also report two cases of pregnancy following fibroid irradiation. The first became pregnant about nine months after treatment and was delivered of a large stillborn child. The second became pregnant one and one-half years after treatment and was delivered of a normal child at term.

It is probable that in all the cases cited all types of irradiation, including short wave and long wave therapy, were used, as the statistics extend over a sufficient length of time to include the periods of prevalence of both types of treatment.

We are, of necessity, considering two different conditions: First, the effect of irradiation on germ cells previous to fertilization and second, the effect of irradiation on the fertilized ovum in its different stages of development.

Under the first consideration, in view of the various reports, we must believe that the ova will be definitely disturbed in a high percentage of cases by irradiation. It is the contention of the German school that this disturbance, if irradiation is pushed to a sufficient degree, will result in destruction of the ova and graffian follicles, and that by this destruction the common results are obtained on all menorrhagias, metrorrhagias, and fibromyomata. The French school contends that these results, especially in the case of fibroids, are due to direct action on the tumor cells and endometrium. They do not, however, dispute the ovarian effect manifested by the cessation of menses and the production of distorted feti.

The second part of our statement would seem to be the one most difficult on which to draw any definite conclusion, in that only six clinical cases have been reported. If we can base our conclusion upon animal experimentation, there seems to be much evidence that definite developmental defects will be noted following fetal irradiation in utero; especially there seems to be proven by Archangelsky's work the fact that the pregnancy may be terminated during the first three months by irradiation of ovum and uterus. These experimental findings have been quite well borne out by the clinical evidence in the case reports cited.

This would necessarily bring up this question:

To how much exposure may be subject pregnant patients in radiographic work? Horner does not believe that there is any danger up to 3000 m. a. s., this being the limit in 250 cases which he had handled, each of which had had some radiography. He has never noted any influence of the exposure on the fetus. I have personally, in a number of cases, made gastro-intestinal examinations on pregnant patients in the first to eighth month of gestation, with exposure, chiefly abdominal, varying from 2000 to 4000 m. a. s., without noting any effect upon the fetus. There is, however, one case in my series in which there was a total exposure of about 5000 m. a. s., including a gastro-intestinal examination and two stereoscopic sets of the pelvis and fetus, one at seven months and one at about term.

In this particular instance, the child's birth weight was six pounds (2.7 kg.), and her progress has been very slow. She is now eleven months old and weighs slightly less than sixteen pounds (7 kg.). There are no definite mental symptoms nor findings, but the child does not conduct herself as does the average child at the same age. She does not speak, is rather apathetic, and dentition has also been delayed.

I have never associated the amount of radiographic exposure in this case with the child's deficiency. However, in view of the literature noted in the preparation of this paper, I believe that the exposure was a definite etiologic factor in the underdevelopment of this child.

We may only speculate on the influence of irradiation on the general development and well-being of the child noted above. However, it has been my good fortune to observe one case of particular interest in which I am certain x-rays played a part in the production of a child below normal—not permanently, but for the first two years. Acknowledgment is hereby made of the assistance of Dr. M. P. Burnham and Dr. F. H. Rodenbaugh of San Francisco in the handling of this case.

Mrs. A., housewife, age 29. April 10, 1921. *Family history*—Negative. *Past history*—Nothing of significance except the history of being a bleeder. *Menstrual history*—Began at thirteen, regular, with severe dysmenorrhea until a few years ago, flow lasts six to seven days, profuse first two days. Last period began December 22, 1920; was normal. Expected date of confinement September 29, 1921. *Previous pregnancies*—None. Married in 1914. *Abnormalities during present pregnancy*—Except for usual nausea and slight show of blood on March 14, patient was well until one week ago, when she had an attack of pain in region of left scapula, suggestive of acute pleuritis. Three days later pain appeared in pelvis and involved both sides, more marked on left, radiating down left leg. Pain was very severe and had to be controlled with morphine.

Physical Examination—Young woman of slight build, rather undernourished and anemic in appearance. General condition fair. Fundus about two fingers below umbilicus and pushed to right, where patient states it has been for some time. Mass about size of a large grapefruit felt just above pubis; firm, but not nodular. Another mass, movable, about size and shape of a medium-sized banana on left side attached low and extending upward. Abdomen very tender and sensitive, especially over tumor masses. *Vaginal examination*—Cervix hard, showing round tumor mass as above described; cervical canal not located; impossible to insert finger between tumor mass and pubis; small movable mass to the left and passing upward toward cul-de-sac, about three centimeters in length and two centimeters in diameter. The whole uterus has been pushed, or drawn, as the case may

be, upward until its actual size cannot be exactly ascertained. The whole abdominal and pelvic structures are tender and sensitive to touch. *Diagnosis*—Multiple fibromyomata complicating a pregnancy of about four months. *Comment*—The factors in all irradiations were as follows: Ninety Kv—5 ma—12 minutes FSD 25 cm.—Filter 5 mm. al. Both anterior and posterior fields were used. *April 19*—After roentgen treatments on April 15, 16, and 18, patient states that pain has been markedly relieved. *April 24*—Pain has been absent for several days, no symptoms whatsoever. Patient eats and sleeps well, gaining in health. *May 10, 1921*—Patient states she has been free from pain for past two weeks; feeling very well, and can perform her usual household duties. Another irradiation given on this date.

Abdominal Examination—Abdomen only slightly tender, and that on deep pressure over tumor masses. Tumor mass which involves the cervix has decreased slightly in size. All other tumors decreased considerably. Patient was able to come to the office alone for examination. *May 12*—Irradiation. *June 8*—No pain since last examination, eats and sleeps well, no discomfort whatsoever. Fetal movement marked and vigorous. Patient states that she first felt fetal life on May 18. *Physical examination*—Shows cervical tumor mass about size of an orange, all other tumor masses not palpable. *Vaginal examination*—Cervix has not regained its identity, but is not so hard and not sensitive. Uterus is coming down farther into pelvis, two fingers can be inserted between tumor mass and pubis. *September 26, 1921*—Since last record, patient has had some pain, never extremely severe, mostly in left lower quadrant. She has gained from 115 pounds to 145 pounds in weight, and general condition has been good.

Physical Examination—Blood pressure, 120-60. Fundus to thirty-eighth week. Tumor mass rather soft at cervix, about the size of an orange. One tumor mass about 5 cm. in diameter, and 2 cm. thick just in front of head in left lower quadrant.

Operation—September 27, 1921. Median incision. Conservative Cesarean section, subserous myomectomy.

Findings—Uterus found twisted to left with right tubo-uterine junction anteriorly. Exploration revealed about eight small subserous myomata scattered over uterus, ranging in size from a pea to a walnut. One large myoma about 6 cm. in diameter and 9 cm. long at the left and including the cervix. In cutting through the uterine wall, it was noted that the thickness was greater than normal, and quite fibrous. A female child was delivered, and breathed before the cord was severed. Four of the largest and most prominent myomata, exclusive of the large cervical tumor, were removed, being easily enucleated. Due to the fact that patient wished to become pregnant if possible, and also that the blood loss had been much greater than in the average case, it was deemed advisable to allow the uterus to remain, as total hysterectomy would have been necessary to remove the large myoma.

Except for a moderate rise in temperature for the first seven days post-operative, her convalescence was uneventful and she returned home sixteen days from the time of her operation, in as good a condition as the average Cesarean section at this time. The child was apparently normal, weight five pounds (2270 grams), cried vigorously, nursed well and conducted itself as a normal infant should. The myoma remained regressed somewhat, but there was some pelvic pain, and further irradiation was administered on the following dates: October 30; November 8, 15, 23, 28; December 6 and 13, 1921; and January 17, 1922, the factors being the same as in the previous treatments except the time was decreased to eight minutes, and the voltage increased to 105 Kv.

The myoma following these treatments disappeared entirely, and the patient was in excellent health six months after delivery. Her menses had not appeared at this time.

The child at this time, however, was rather frail and anemic, and while there was no definite deviation from normal, she was below par physically and mentally.

All effort to establish direct communication with this patient since that time has been fruitless, but the observation of a colleague six months ago was to the effect that

the child was at least one year mentally and physically backward.

Dr. Rodenbaugh informs me that he has very recently observed both mother and child. The child, to all intents and purposes, is normal. The mother's general condition is excellent; her menses have returned and all myoma are absent, the uterus being small and fibrous.

CONCLUSIONS

1. Pelvic irradiation of females who may become pregnant should be done with much care in selection of cases, and either only very light dosage employed or complete castration effected.

2. Pelvic irradiation of pregnant females should not be done except where there are very extenuating circumstances, and in any event the patient and her husband should be informed of the possibility, if not probability, of a deficient child.

3. Irradiation during the later months of pregnancy, if conclusions may be based on the results in six cases, is less injurious to the fetus than irradiation during the early months.

4. It would seem that the longer the elapse of time between irradiation and subsequent pregnancy, the greater is the probability of a normal child being born.

5. Radiography should be limited during pregnancy to the minimum.

6. Roentgen abortion or castration should never be performed except where there are definite reasons why the ordinary surgical procedures should not be followed.

7. There seems to be little difference between the actions of long and short waves on ova, either fertilized or unfertilized.

DISCUSSION

FRANCIS B. SHELDON, M. D. (Mattei Building, Fresno, Calif.)—This very interesting paper shows much work. However, it seems to me that we have not yet done enough work on this subject to form very definite conclusions. Certainly, we will all agree that the fetus in utero should not be exposed to more than a minimum of ray with which we may accomplish the purpose for which we are making the exposure. We should not accuse the ray of results, when we do not uniformly get those same results following exposure to the ray. There is much filtration of the ray before it will reach the fetus in utero.

Very often in families where there are several children we will see one or another that will apparently be more backward than others. Or they may not grow and develop as rapidly as some of the others. Families in which this occurs may never have been near an x-ray. We have not determined the reason of this backwardness in one child and not in the others. Until this is determined, how are we to have perfect controls to determine the actual lesion that may be produced by the ray? There has been no fetal lesion reported following radiation that cannot be found where no radiation has been given. We have all rayed pregnant women and seen no ill-results in the child after delivery.

Until we have ruled out all the causes for the deformities and backward conditions in children, we should not be too hasty in placing the blame for these things on the x-ray. This does not eliminate caution in our work. In the case reported, can we definitely say that the condition for which the radiation was given was in no way responsible for the temporary backward development of the child? I do not believe that we should blame the ray for results that are more or less common without its use.

KURT F. BEHNE, M. D. (Soiland Radiological Clinic, Los Angeles)—The very interesting article of Dr. Lawson touches a problem which is, next to the treatment of cancer, the most important one in modern radiation deep

therapy. It is an established fact that we are able to produce the menopause by roentgen or radium rays at any age of the patient without causing any damage to the skin or to any internal organs. The observation of patients who have undergone this treatment during the last ten years has proven that the after effects of the "radiation-menopause" do not differ from the bodily changes happening during the course of the natural menopause. The experiences in Dr. Soiland's Radiological Clinic corroborate this.

Provided a proper indication is present for an artificial menopause, we are justified in producing it by the rays without restriction in cases of women who are nearing the menopause. The question is whether we are generally entitled to cause the "radiation-menopause" in women who are still in the child-bearing age. Of course, we are allowed to stop the menstruation permanently by the radiation treatment in younger women as is the surgeon who extirpates both ovaries, provided there is a proper indication for this treatment. Another question is whether we are allowed to give the patient the radiation treatment in cases in which the surgeon is able to relieve the condition by a conservative operation, not disturbing the function of the ovaries, as, for instance, in cases of myomectomy. The experience of Gauss, Seitz, Wintz and other authors has shown that we can obtain, in proper cases, the same results as the surgeon with his conservative operation without endangering the life of the patient and without hospitalization, by the "temporary stopping of the menstruation" for a half year or longer with the administration of an adequate roentgen ray or radium dose. Within this time the diseased condition of the genital organs clears up (myoma, irregular and excessive menstrual flow, inflammation, etc.) and the patient again starts menstruating normally.

Up to the present time, there has been no damage observed in the children borne by women with regularly functioning ovaries after such a temporary stopping of the menstruation with the radiation treatment. The biological happening in the ovaries after the absorption of such a small radiation dose and the harmlessness of this dose as to future pregnancies can be easily explained. There is a difference in the radiation sensitiveness of the various stages of evolution of the ova. The primordial follicles are apparently much less sensitive to the rays than the Graafian follicles. The small dose of rays destroys the function of the Graafian follicles, but does not affect in any marked degree the less sensitive primordial follicles. As soon as the slightly disturbed primordial follicles have developed into Graafian follicles, the normal function of the ovaries starts again and the menstruation again appears. It is evident that the ripe ova which originate from these follicles have not been affected by the small radiation dose which was necessary for the temporary stopping of the menstruation. The appearance of an entirely normal menstruation shows also that there is no longer a disturbance of the function of the ovaries, and for these reasons any fears of finding either bodily or mental disturbances in a child born after such a radiation treatment of the mother are without foundation.

I agree with Lawson that the administration of rays should be done only in cases where it is properly indicated. I think, however, we should use the rays more extensively in cases of benign diseases of women in the child-bearing age instead of surgery.

The case of Stettner, referred to by Lawson, is well known to me, Professor Stettner, Erlangen, being a personal friend of mine. The patient had been treated in our University Women's Hospital in Erlangen, Bavaria. What Sheldon says in his discussion applies also to this case. It cannot be positively determined whether the disturbances of the child are due to the x-ray treatment or due to other unknown causes. A myomatous uterus as such is liable to cause failures of development in a child.

FREDERICK H. RODENBAUGH, M. D. (516 Sutter Street, San Francisco)—The patient referred to by Dr. Lawson was observed by me during treatment, and observed two years following treatment, shows two distinct phases of the effects of radiation:

First, the difficulty with moderate radiation in producing complete and permanent amenorrhea in young women. The restoration of the menses in varying periods of time following treatment is the rule in young women.

The child at this age does not present any marked mental or physical stigmata to differentiate it from the average child of its age.

I was most reluctant to treat a pregnant uterus, and was only induced to do so when an abortion was imminent, and while my personal experience is limited to two cases, neither of them received massive radiation, and I was fortunate in not producing deformities in the children. I believe that the administration of heavy radiation to pregnant uteri will conform to experimental data, and produce defective offspring. I do not believe that I will personally administer therapeutic doses to any pregnant uterus in the future.

It should be clearly understood, however, that there is no danger in the use of the ordinary diagnostic measure, and an impression should not be given to the general profession that harm will result from diagnostic procedures.

Doctor Lawson is to be congratulated on his clear presentation of the subject, and his careful review of the literature, and I fully concur with his conclusions.

DOCTOR LAWSON (closing).—It has pleased me very much to have a full discussion on this paper, inasmuch as I have experienced very much interest in the collection of the data which has been put into the article.

I fully agree with Sheldon in his statement that there has been no fetal lesion reported following the irradiation that cannot be found where no irradiation has been given, but I really feel that the incident of fetal lesions is infinitely greater in cases where irradiation has been given than in cases not so treated. I think this opinion is verified by the literature.

Behne states: "Up to the present time there has been no damage observed in the children borne by women with regularly functioning ovaries after such a temporary stopping (by irradiation) of the menstruation."

This, however, is not borne out either by experimental data or by cases cited in this paper, especially the work of Clark and Keene, Werner and Stacy. There is no doubt that we are in the dark to a great extent as to results directly traceable to irradiation and the many variable conclusions bear witness to this fact.

DIPHTHERIA IMMUNIZATION

By ABRAHAM METZNER, M. D., Los Angeles

The increased and increasing knowledge of diphtheria should be constantly utilized by all physicians.

It is as much a physician's duty to prevent his clients from contracting diphtheria as it is to treat them after they have it.

Preventive methods are simple and certain, and can be used by any intelligent physician in his office.

DISCUSSION by William C. Hassler, San Francisco; Langley Porter, San Francisco; Clifford D. Sweet, Oakland; Edgar Brigham, Dinuba; J. W. Morgan, Modesto; J. D. Dunshee, Los Angeles.

DIPHTHERIA is still one of the most dreaded diseases and one of the most frequent causes of death in early childhood, and it is a fact that the discovery and use of antitoxin has materially reduced this death rate. The death rate has dropped from about 65 per cent to about 10 per cent. At this latter figure it has remained, in spite of our clearer knowledge of the disease and improvements in diagnosis and treatment. That no further decrease in the death rate has occurred, is due to the human agencies rather than to limitation of the value of antitoxin. The poor resistance of patients, their inability to manufacture a natural resistance, and the too frequent failure in early administration of sufficient antitoxin are among these causes. B. S. Roberts of the New York State Health Department found, in an analysis of over 500 deaths from diphtheria, that the death rate is practically nil when

adequate treatment is given on the first day of the disease. This has been corroborated by others. The fact also remains that, when contacts are given antitoxin as an immunizing agent, the period of immunity is brief, no provision being made for susceptible contacts who are not discovered. The carrier problem is also present. Atypical and nasal diphtheria often pass unnoticed. Antitoxin is not entirely without danger, and deaths from its use, though few, have occurred. It will thus be seen that further measures are extremely necessary. Thanks to the work of Behring, Schick, and others, the dangers from additional factors can be aborted, and diphtheria so controlled that, eventually, it will become one of the diseases more rarely seen.

Lesions of diphtheria, both local and general, are due to the action of a soluble toxin secreted by the Klebs Loeffler bacillus. How they act is still a moot question. Recovery takes place through the formation of antitoxin by the body cells, which neutralizes the toxin. That permanent immunity is not produced by the disease is evident, in that two or three attacks are not very uncommon. A natural immunity is frequently present at birth and may last through life. Von Groer and Kassowitz found that those mothers who had a natural immunity were able to transmit this immunity to their offspring, while the 16 per cent of the mothers who did not possess this immunity had offspring who were not immune. These findings were more recently corroborated by Ruh and McClelland. This immunity, however, is lost in fully 85 per cent of the infants by the age of six months. Those losing this immunity reacquire it in a progressively increasing number as they grow older, but, as a rule, it is not reacquired before the ninth year, thus leaving them vulnerable during the most susceptible age group between six months and nine years.

The problem then remains to separate the immune from the susceptible and to immunize the non-immune. In 1913, Bela Schick proposed a very simple method of separating these groups based upon the observations of von Behring. Schick discovered that when 1/50 of an M. L. D. for guinea pigs weighing 250 grams was injected, intracutaneously, in a human being in whom there was 1/30 or more of antitoxin per cubic centimeter of serum, no reaction followed. If less than this amount, or none at all was present, it produced an inflammatory reaction at the site of the injection. This inflamed area persists for four days or more, and should not be confused with a somewhat similar reaction which may be produced by the protein found in the diluent, and which disappears within twenty-four or thirty-six hours. Von Behring, following the method used by Park and others in immunizing animals, showed that the same procedure could be safely used in humans. In 1920, Bieber published a history of 1097 children who had been immunized by Hahn and Sumner, in the village of Madgeburg in 1913, showing that of those who had received full treatment of toxin-antitoxin, only 3.3 per cent later developed diphtheria, while of those who had not been immunized, 15 per cent developed the disease, thus reducing the incidence by approximately 80 per cent.

From that time on, there has been an increasing

volume of reports corroborating these results. The first work on a large scale was done by Park, Zingher, and co-workers of the New York Health Department. This placed the work on a solid foundation, and served as an impetus to other communities throughout the country. As a result, most of the larger cities have undertaken this work as a routine measure, most of them working through the public schools and health boards. Consequently, there has been reported a distinct lowering of the incidence of diphtheria in those communities.

The toxin-antitoxin is prepared according to the method worked out by the New York City Laboratory, and is supplied by several of the reputable commercial houses in convenient containers for immediate use. This preparation contains 1/10 M. L. D. of toxin to the dose, and is sufficient to immunize without causing any untoward reactions, in contradistinction to the preparation used until the first of the year, which contained 3 M. L. D. The toxin-antitoxin is injected preferably intramuscularly in three doses of 1 cubic centimeter each, at weekly intervals.

It would seem that the following facts have been proved:

The use of antitoxin has about reached the limit of efficiency in reducing mortality.

The highest percentage of susceptibles are among children between the ages of 6 months and 9 years.

The Schick test is a reliable method of separating the immune from the susceptible.

Toxin-antitoxin given in three doses at intervals of one week will actively immunize about 85 per cent of the susceptibles.

This problem is, in my opinion, a health board problem, and in many of the larger communities it has been taken up by public health department with very encouraging results. In Southern California, we are laboring under a serious, difficult condition because of the great political strength of the anti-medical groups. We are completely shut out of the public schools in this work, and are, therefore, unable to reach the public through that channel. The board of health is also hampered by a paucity of nurses and physicians, and an inability to secure sufficient funds.

In Los Angeles, diphtheria immunization has been carried on since 1919 in some of the orphanages and other child-caring institutions. Where it has been adequately supervised, diphtheria has been almost entirely eradicated, but in those institutions where this work has not been done, they still have their customary yearly quarantines from diphtheria. Conditions in the county outside of the city of Los Angeles are much better in this respect, because of better organization and contacts with other communities and schools. It has been possible to reach a much larger number of children, and to date over 3000 children have been immunized.

In November, 1923, this work was begun at the Anita Baldwin Clinic. This was the first attempt in this city to reach the children outside of institutions. Later the city health department offered to supply free toxin-antitoxin. At the onset of the work a few of the children and nurses were "Schicked," with results corresponding to those published by

other writers, namely, that over 80 per cent of positive reactions were obtained in the younger children, whereas only 9 per cent of the nurses were Schick positive. Since this first series, we have not given any initial Schick tests in the children under 9 years of age. This method is also being followed in many other communities. However, we are "Schicking" all of them three months after the last injection of toxin-antitoxin. Thus we are able to simplify the procedure and require fewer visits to the clinic. We have had very good response from the mothers bringing their children to the clinic, and very few have refused to have their children immunized when the procedure was explained to them. To date we have given 432 injections of toxin-antitoxin, and 91 Schick tests. This number is too small to be of any statistical value. We hope to be able to publish a detailed account of our work at a later date. This work is being done without publicity or other outside aid in interesting the parents.

More recently, a plan has been devised which may be productive of good results. A life insurance company has agreed to co-operate, and will instruct their nurses to work with the city health nurses in canvassing the homes in two districts which will be definitely outlined. The children in these districts are to be referred to the Anita Baldwin Clinic and the Children's Hospital. While much good may be accomplished by such a campaign, it will require the active co-operation of the physician to be of maximum benefit. This applies particularly to the general practitioner, who sees the bulk of the children.

It must be recognized that, as physicians, we have a moral obligation to the public; that while we are in the favored position of being better informed on health matters, it is our duty to impart that knowledge to those who are less adequately informed. This movement is one of the many, which, from time to time, we will be obliged to carry forward, and it is by such steps we will still further add to the confidence of the public at large, so valuable to the cause we lead and espouse, and in physicians who serve that cause.

902 Union Bank Building.

DISCUSSION

WILLIAM C. HASSLER, M. D. (Department of Public Health, San Francisco)—Perhaps once in each generation of human existence is a discovery in medicine made that equals the importance to the human race of that of toxin-antitoxin as a prophylactic and preventive of diphtheria.

Doctor Metzner says that the death rate from diphtheria has decreased very little in the last few years, because of the failure of human agencies. Naturally, there is a twofold reason for this: First and most important in the absence of toxin-antitoxin immunization, the physician is not called or the diagnosis is not made until so much of the diphtheria toxin has combined with the tissue cell that the antitoxin is not as effective as it would be if earlier recognized and administered. Secondly, many failures in the use of the Schick test are due to improper technique, and no doubt a considerable percentage of cases are classed as "immune" that should, because of this failure to get a proper Schick reaction, receive toxin-antitoxin. When we have learned this technique, we may be able to reduce the death rate still lower.

Diphtheria, before the advent of antitoxin, was a disease that gave more or less immunity against subsequent infection, but since the antitoxin has come into general use this is not a fact, because antitoxin administered during the disease inhibits the manufacture of natural antitoxin

in the blood stream, and this antitoxin artificially administered is eliminated in a short time, leaving one almost as susceptible to infection as before. I agree with Dr. Metzner that a Schick three months after the administration of toxin-antitoxin is of more importance than a preliminary Schick, because experience has proven that, in a certain proportion of cases, three doses of toxin-antitoxin mixture was not sufficient to produce immunity, and those cases should be known and receive further treatment. We, in San Francisco, have recently had this experience in a group of school children that were Schick tested, received toxin-antitoxin, and out of one class five cases developed diphtheria. No great effort has been made in San Francisco to force the Schick test, but we are spreading propaganda by circular and by discussions of the subject through our school-nursing division and health centers. We find that an increasing number of parents are inquiring and ask for this protection to their children.

LANGLEY PORTER, M. D. (380 Post Street, San Francisco)—The contribution of Dr. Metzner on diphtheria immunization is most timely, and it will be of value if the profession in California will accept the big message, which is that it is needful and useful for all health agencies—state and local—ceaselessly to inform the public that diphtheria is a preventable disease. Imperative as it is for these agencies to provide the machinery by which any child in the community, whose parents desire it, may be immunized, *it is only through the aid of the individual physician practicing in his office that the full benefit of the discoveries of Behring, Schick, Zingher and Park, can be made fully available to the community.*

Some physicians are issuing a statement of the value of the toxin-antitoxin immunization to their patients. To my mind, it would be a valuable disease preventive measure if the boards of health would supply a printed slip which could be enclosed in every bit of correspondence that leaves the doctor's offices—a slip which might ask, "Is your child protected against the deadly disease, diphtheria? If not, why not? The use of toxin-antitoxin is a proven preventive, your doctor is prepared to advise and serve you."

As to the technique, the method of the New York Board of Health is based on wide experience, and should be accepted as the standard. The reaction to the first injection can be used as Park uses it—to replace the preliminary Schick test in young patients. As Hassler emphasizes, the Schick test, following three months after the immunizing course, is most important in order to check the acquisition of immunity. *Not less important is it to instruct parents and teachers that the three months following the immunizing course is a time of susceptibility, else we will have the ignorant and vicious pointing of the finger of scorn and saying, "The toxin-antitoxin—oh, that is a fake of the doctors. Smith's Johnnie and Jones' Katie, they got diphtheria a few days or a few weeks after they were given the serum."*

CLIFFORD D. SWEET, M. D. (440 Seventeenth Street, Oakland, Calif.)—I am glad, indeed, if I can emphasize the importance of diphtheria immunization by means of toxin-antitoxin. *Only by means of continued work and this matter ever be satisfactorily presented to the public.* The mother's natural reluctance to submit her healthy enthusiastic propaganda by all practicing physicians can child to even a fancied inconvenience can only be overcome by her physician pointing out its advantages and its lack of any real danger. Since the 1 plus L dose has been used, we have had few, if any, severe reactions. It is very important that the mother be told of the possibility of failure to completely immunize the patient. In my experience three months is a somewhat too short time to allow immunization to become complete. We direct our patients to return in four months for the Schick test.

I hope many others will follow Doctor Metzner's example and present this matter back to the general and medical public at every opportunity.

EDGAR BRIGHAM, M. D. (Dinuba, Calif.)—The toxin-antitoxin treatment is without doubt the most important recent prophylactic measure to be used. I agree with Doctor Metzner that it is, however, essentially a health board measure, as the opportunity for carrying out the

tests and checking results on a large scale, is, with few exceptions, confined to public service.

Doctor Sweet considers it best to wait four months after the toxin-antitoxin injection before making the Schick test. In view of the experience of Sears, Zingher and others, it is probable that the longer period would show more negative reactions.

As practicing physicians, our duty is to support our local boards of health as the most active agents of preventive medicine.

Metzner announces a truth which ought to be actively accepted by every member of the profession, when he says: "It must be recognized that, as physicians, we have a moral obligation to the public . . . to impart knowledge to those who are less adequately informed."

J. W. MORGAN, M. D. (Modesto, Calif.)—It is to be hoped that Doctor Metzner's article will be read by every physician in the West, as it is through co-operation by the individual family medical advisors that the parents will see the light. We have had splendid results in Modesto. During the past ten months we have immunized over 1400 children. *The City Council donates the toxin-antitoxin, and the parents are advised by the health department through the press to go to their own physicians for the treatment. All members of the local medical society agree to give the treatment for a nominal sum (\$3 is charged), and everyone has co-operated.*

This method does not allow for proper Schick-testing, but it gets the children immunized. We are now able to tell the public that if they have diphtheria it is due to neglect. *To date the cost to the City Council has been less than \$250, and everyone is of the opinion that the physicians are taking the proper attitude.* Our greatest difficulty has been to convince the parents that children under school age are so susceptible. It is our plan to advertise every case of diphtheria reported so that the parents will finally have the great majority of their children immunized. We also stress the fact that three months' time must elapse before the immunity will be active.

J. D. DUNSHEE, M. D. (Department of Health, City of Los Angeles)—The city health department has been much handicapped in this work which might have been and should be done in Los Angeles, due to the fact that they do not have admission to the public schools. They have been Schicking all the inmates of two of the largest institutions in the city, and giving toxin-antitoxin to those showing susceptibility for the past four years, and have endeavored to do the same in other institutions, but up to a very recent time have been unable to get their consent to do this.

It is well understood among health workers that health programs are exceedingly more difficult in cities of any size than in the smaller communities, which is largely responsible for the fact that the smaller places of Los Angeles County have received this better.

We have been able to go into the outlying districts of the city and easily secure the consent of a majority of the parents in this work.

One of the greatest obstacles we have met is the general apathy of some physicians and the opposition of a few who seem to have considered, or, at any rate, advised families under their care that the administration of toxin-antitoxin is dangerous.

DOCTOR METZNER (closing)—I have very little to add to the discussions. In regard to allowing four months to elapse before giving a re-Schick, as suggested by Doctor Sweet, I can see no objection to such a procedure. I feel, however, that it is practically as reliable to re-Schick in three months, and it is easier to keep in touch with the patient for the shorter length of time. Each parent is requested to have another Schick test made in six months.

Think of the dancer, Lotta, who accumulated \$4,000,000, and died at the age of 74 in Boston four months ago. She left her money, a large part of it, to PREVENT the investigation of disease through the study of diseases in animals. It isn't fair to the beasts, to the animals of the world, to allow them to go on dying when we are taking care of ourselves, but the highest work that any animal in the world can do is to furnish evidence for the protection of human life.—C. H. Mayo.

SURGICAL AMEBIASIS

By P. K. GILMAN, M. D., San Francisco

Proper drug treatment cures a large percentage (85 to 90 per cent) of cases of amebiasis with one course. A small number will require a second course. A still smaller a third.

Of the remaining small number, the majority suffer reinfection from a focus either in the appendix, gall-bladder, or both. Removal of these foci is followed by permanent cure.

DISCUSSION by Alfred C. Reed, San Francisco; Wilson T. Davidson, San Francisco.

AMEBIASIS is not limited to tropical and subtropical countries. It is widespread in its distribution, and occurs in practically all parts of the United States. Here in California the cases of infection with *A. histolytica* are on the increase.

The disease—infection with *A. histolytica*—may manifest itself through a great variety of symptoms. One of these is dysentery, at times the predominant one. The disease should not, however, take its name from one symptom and, therefore, amebic dysentery is not a good term; in fact, is misleading, as often no dysentery occurs during the entire course of the disease.

Amebiasis is to be preferred. Its symptoms may be definite or extremely indefinite; may be concerned with the gastro-intestinal system and suggest peptic ulcer with either normal-appearing or very costive stools; may center in the neuro-muscular apparatus, with various nervous manifestations and muscular pains.

In addition to persons presenting sufficient symptoms to be classed as ill, there is a group of "carriers"—people with cysts and at times motile amebae in their stools who consider themselves as not suffering from amebiasis. Is any so-called carrier perfectly well? The majority probably are not, if sufficiently painstaking investigation be made.

While the treatment of amebiasis is medical in over 90 per cent of the cases and of these from 85 to 90 per cent are cured by one course of treatment, some cases will require a second, and a few a third course in order to cure by medical means. In addition to this major group a smaller group will resist any or all known forms of medical treatment. These cases become surgical.

The surgical cases may be fitted into three main groups:

1. Cases requiring surgery to assist medical measures directed toward clearing the bowel of the amebae, the disease being limited to the bowel.
2. Cases complicated by disease set up by the organism beyond the limits of the bowel.
3. Cases "incurable" by medical means to remove at operation organs now known to harbor the organism and act as foci of reinfection of the gut. These cases are cleared of the organism by medical means temporarily only.

In the first group, dysentery is the important symptom, either acute or chronic. The patient either shows no signs of improvement with drugs, diet, and rest, or becomes worse.

Surgery should here be considered early, and has for its object putting the diseased bowel at rest.

This may be attempted by appendicostomy, by cecostomy, or by ileostomy.

Appendicostomy was introduced largely for purposes of lavage until the x-ray showed us how completely and promptly all parts of the large bowel may be reached from below via the rectum. However, appendicostomy undoubtedly has a value in certain cases.

Cecostomy is to be preferred to appendicostomy, as being followed by more complete rest of the large bowel. However, this rest is far from satisfactory, as some bowel contents will pass across the opening. Compared to ileostomy, cecostomy is more simple and possibly more readily closed, but is less effective.

Ileostomy is followed by absolute rest of the large bowel, and the relief of symptoms is immediate. With the ordinary ileostomy, a second operation, of course, is necessary to restore the continuity of the bowel. The more recent method of forming a double diaphragm, as used by Stone of Baltimore, meets this objection.

In the second group occur the abscesses, empyemata and granulomata resulting from the action of the ameba beyond the limits of the bowel wall.

Pulmonary abscess is not rare. It usually follows an abscess below the diaphragm, but at times is primary. It may rupture into and drain through a bronchus, and at times cures itself spontaneously. More often, however, added surgical drainage is needed.

Amebic abscess of the liver, if of any considerable size, is surgical and demands drainage. Hepatitis, and at times small abscesses, may yield to medical measures. We prefer the abdominal route in attacking hepatic abscess, as the surrounding structures may be explored and there is a minimum danger of peritonitis, the amebic pus usually being sterile. After drainage is established, the administration of emetin hastens materially the healing and shrinkage of the abscess cavity.

Abdominal abscesses are rare, when one considers the condition of the large bowel in a well-developed case of infection. Bacterial infection is, of course, added.

Perinephritic abscess is met with occasionally. It follows spread of material from the colon direct or indirectly from an abscess of the liver pointing downward.

Of considerable importance are amebic granulomata. These inflammatory masses occur in relation to the wall of the large bowel, usually at the flexures, and, clinically, strongly suggest new growth. We have seen two cases subjected to resection for supposed malignancy. Their treatment is medical, rarely surgical, and then only for obstruction.

Less common abscesses are those occurring in the brain and in the spleen.

The third group of cases which are surgical includes those where medical treatment has failed. The so-called "carriers" are placed in this division.

The important question is, when has the drug treatment failed? My associate, Gunn, holds the case incurable medically, if the amebae appear in the stool during a course of combined emetin and salvarsan treatment after the salvarsan has been ad-

ministered, cases not responding promptly to the drug treatment and cases where amebae reappear in the stool after three complete courses of the combined treatment, as outlined by him.

Are there any true "carriers"? Very few if any. If a careful history and examination of such persons be made, it is usually possible to elicit more or less definite symptoms due to the infection. These symptoms may be referred to any part of the gastro-intestinal tract or to the neuro-muscular apparatus.

In the above cases, foci of reinfection exist in association with the gastro-intestinal tract, where the amebae lodge and where the circulating drugs fail possibly to reach them in sufficient concentration to kill. Removal of these foci will lead to a cure, at times without any further medical measures.

The appendix and gall-bladder are both possible foci for reinfection of the intestine. The former has been known, for some time, to harbor amebae in its mucosa. Amebic ulceration of the appendix often produces typical symptoms of appendicitis.

Crowell, in Manila, some years ago demonstrated amebae in the wall of the gall-bladder, and we have confirmed this on several occasions. Patients long considered incurable have been cured following cholecystectomy and appendectomy.

SUMMARY

Proper drug treatment cures a large percentage (85 to 90 per cent) of cases of amebiasis with one course. A small number will require a second course. A still smaller a third.

Of the remaining small number, the majority suffer reinfection from a focus either in the appendix, gall-bladder, or both. Removal of these foci will be followed by permanent cure.

350 Post Street.

DISCUSSION

ALFRED C. REED, M. D. (380 Post Street, San Francisco)—I think this is one of the best summaries I have seen of the subject under discussion. It is comprehensive, and I can only endorse the position taken. I am constantly seeing the surprise of patients that amebic infection can be acquired in California. Yet it is frequent in persons who have not been out of the state, and even is acquired here in the bay district. As the author points out, the term "amebiasis" is much more accurate and descriptive than amebic dysentery. This term was coined by Dr. Musgrave, in Manila. It can be matched or qualified in another term which I have used to describe the prevailing type of this disease as we meet it here. This is "non-dysenteric amebiasis." In hot climates dysentery is a more usual symptom. In cooler climates and in California, it is our experience that constipation predominates as a symptom in these patients, and that many other symptoms are found. Hence, the logic of classifying such cases as non-dysenteric amebiasis. Finally, I want to emphasize the dangers of the indiscriminate and injudicious use of emetin. Emetin is a powerful and poorly understood drug. Its pharmacology is not worked out fully. A certain percentage of patients treated intensively for amebiasis will develop symptoms of weak heart, low blood pressure, and peripheral neuritis. The syndrome has certain analogies to beriberi. It is interesting that, in the Orient, the observation has been made that dysentery treatment often precipitated an attack of beriberi. We need to know more of the action of emetin and to understand better how to intensify its amebicidal effect by diet and other drugs.

WILSON T. DAVIDSON, M. D. (350 Post Street, San Francisco)—I have read with great interest Dr. Gilman's paper, and I consider it a valuable contribution to this important subject. I believe that if these cases were diag-

nosed early and treated intensely, very few of them would develop surgical complications.

We have passed through a period of therapeutic nihilism. Many will recall Dr. Osler's dictum that we had only four specifics. Recently Dr. Hewlitt added quite a number to that list.

Although the life history of the *entamoeba histolytica* has been worked out fairly completely, unfortunately we have no specific for amebiasis. Ipecac has been the favorite remedy since the time when the roots were carried from Brazil to France and sold to Louis the fourteenth as a secret remedy for a select few of his court. To the English in India must be given the credit for popularizing the use of this drug, and it was used as such until within recent years, when the alkaloid emetin was separated. For a few years emetin was very popular, almost to the exclusion of all other remedies. Lilley & Co. put out the alcresta tablets, which were very widely used.

At the present time we see large doses of bismuth, as recommended by Deeks in the Canal Zone, emetin-bismuth-iodine and emetin per iodide, as used by the English; yatrin, a combination of iodine, oxy chinolin and sodium sulphate, as used by the Germans, and various preparations of arsenic and emetin, as used by the French. Chaparro armagosa or bitter root, as a decoction, now has its strong advocates; and recently, with the prevailing tendency to cure everything by intravenous medication, arsenic preparations and the penetrating dyes are coming into vogue. We also see mercurochrome used both by mouth and by way of the colon.

Twenty-five years ago, when I first began the use of ipecac in Cuba in the treatment of amebic dysentery, I found that the symptoms rapidly subsided, and I thought that my patients were cured. However, no laboratory examinations were made and no doubt many of them were not cured, became chronic cyst excretors, and quite likely developed just such surgical complications as Dr. Gilman has described; and I would like to emphasize the point that today amebiasis patients are still discharged as cured as soon as they are free of symptoms, and one stool is pronounced negative.

Personally, I put these patients to bed on a liquid diet and give a combined course of emetin hypodermically, three grain capsules of emetin-bismuth-iodine, and at the end of the week .9 of neosalvarsan. This completes the course, and in 90 per cent of cases is effective in rendering the patient free from parasites. However, it may be necessary to repeat the course one or more times.

No patient should be dismissed until one is reasonably sure that he has been rendered free from the infection. This is by far the most important point of all and one to which particular stress has been given by Herbert Gunn.

As a working method, I usually examine the second week, after a course of treatment, a formed stool; then give the patient a dose of salts, and examine a liquid stool with ample fecal matter. Then, afterwards, another formed stool. This is repeated the following week. Then, in the course of five or six weeks, a series of stools are examined: five or six formed stools, and three or four liquid stools. This is repeated the following month.

By giving salts and examining the stools while they are warm, you get the motile forms. During the entire course, twenty-four formed stools and twelve liquid are examined. If such examinations are made with negative findings over a period of three or four months, one can feel quite confident that his patient no longer harbors infection in the colon.

Examining the Well Person—The best post-graduate course that the American medical profession could have at the present time would be to learn how to examine the well person. We should examine every case from head to foot, no matter what the complaint. If we had that sort of routine and uniformity of examination in our individual practices, what wonderful doctors we would be. What is our trouble? Lack of knowledge? No. We really don't see many obvious conditions because we don't examine systematically. What better preparation can you have for examining and diagnosing the pathologic conditions than to make it a custom among physicians to examine frequently every individual in their own clientele?—W. D. Haggard (A. M. A. Bulletin).

A SYMPTOM COMPLEX IN DIABETES THAT MAY BE CONFUSED WITH THE REACTION OF INSULIN OVERDOSAGE *

By BERTNARD SMITH, M. D., *Los Angeles*

Symptoms described.

Illustrative case record given.

Significance of the symptom complex not fully understood.

DISCUSSION by Franklin R. Nuzum, *Santa Barbara*; Albert H. Rowe, *Oakland*; P. Berman, *Los Angeles*.

A CONSIDERABLE proportion of diabetic patients develop a rather definite group of symptoms that may easily be confused with many of the symptoms that follow an excessive insulin dose. These symptoms appear most frequently in those patients who had become undernourished to an extreme degree, or who have had some complication that has required vigorous treatment with insulin. The symptoms do not usually appear until the patient has reached a state of apparently adequate nourishment and strength.

Muscle weakness is frequently one of the early symptoms. This weakness usually appears in the middle of the forenoon or late in the afternoon, and is described often as a sense of goneness or a feeling of lack of supporting strength in the leg muscles. It closely resembles the weakness that may be an early symptom from an overdose of insulin. A sensation of stiffness in the muscles may be present during the period of weakness or may be constant throughout the day. This is often felt in both arm and leg muscles. Occasionally, there have been noticed slight spasmodic contractions in these muscles that give the appearance of a mild tetany.

During the periods of weakness, the patient may complain of chilliness. At such times the forehead and palms are moist with a cold perspiration; the entire face shows an ashy pallor; the pupils are dilated; the pulse is rapid and soft; and the hands and feet are cold. When the symptoms are more pronounced the patient may appear to be in severe shock or collapse. The pallor is more marked than in the early symptoms of the insulin reaction, and the cold sweating is more profuse than the slight moisture that precedes the insulin tremor, but is not so general or so extreme as the later sweating associated with the insulin convulsion. Dizziness is a common symptom and may be so severe that the patient is unable to continue at work. There may be various parathesias, and disturbance of co-ordination, together with a dimness of vision. Faintness may be a disturbing symptom, although an actual loss of consciousness has never been reported by the patients. Arterial hypotension has been a constant finding, even when the symptoms have been mild. More recently a gradual lowering of the blood pressure has been found in patients before definite symptoms developed.

These symptoms may be found with patients who have never received insulin. They occur more frequently among patients who have had the aid of the extract. The condition seems to be most common among those patients who have been built up rapidly

to a satisfactory weight, or who have been carried through a short convalescence after some serious diabetic complication. The insulin reaction is always a result of subnormal blood sugar, and the symptoms will vary in severity with the degree of hypoglycemia present. The condition now described may be associated with a normal blood sugar value or with a hyperglycemia. Glycosuria is not uncommon in the period these symptoms remain uncontrolled. Several patients have been kept under observation for several weeks, during which time the sugar excretion has continued at a concentration of from 1 to 5 per cent. This glycosuria is not associated with an increased urine volume or any other of the common diabetic symptoms. An increase in the insulin dosage to clear up this glycosuria may result in a severe reaction from overdosage, with little, if any, effect on the sugar output.

Studies of this condition have not been carried far enough at this time to justify any conclusions as to a definite etiology. Estimations of the calcium¹ and inorganic phosphorus of the blood have been of interest. In twenty-five determinations on twenty diabetic patients who were in good physical condition and without symptoms, calcium values below 10 mgs. per 100 cc. of blood were found in but two patients, and both of these had had symptoms, but at the time the determinations were made they were vigorous and doing manual work. The average calcium value for this normal series was 11.45 mgs. In twenty-nine determinations on twenty-three patients who had symptoms, only seven gave values above 10.0 mgs. The average for this group was 9.01 mgs., with 6.4 mgs. as the extreme low value. Determinations of inorganic phosphorus showed practically the same distribution for the two series, averaging 3.54 mgs. and 3.57 mgs., respectively.

ILLUSTRATIVE CASE REPORT—June 24, 1923. Admitted. Male. Age, 54 years. Weight, 56 kgm. Gangrene of foot. General examination negative, except for gangrene. Blood pressure, 128/80. Urinalysis: Sugar, 1.9 per cent. Diacetic acid trace. Albumen trace. Casts none. Blood analysis: Sugar, 400 mgs. Calcium, 11.2 mgs. Non-protein nitrogen, 2.6 mgs. Diet: C. 60; P. 50; F. 140. Insulin: Ten units twice a day.

AUGUST 30, 1923—Insulin stopped. Diet: C. 90; P. 60; F. 150. Feeling well. Active. Returns to work.

SEPTEMBER 30, 1923—Complains of extreme weakness of leg muscles. Weakness appears about 10 a. m. and 5 p. m. Urinalysis: Sugar, 1.08 per cent. Albumen none. Diacetic acid none. Blood analysis: Sugar, 175 mgs.

DECEMBER 10, 1923—Symptoms have increased. Complaints of inco-ordination, aching and stiffness of leg muscles. Dimness of vision and faintness. Attacks periodic. Feels well between attacks. Blood pressure, 110/78. Urinalysis: Sugar, 0.75 per cent. No acidosis. No albumen. Blood analysis: Sugar, 138 mgs. Calcium, 8.2 mgs.

FEBRUARY 4, 1924—Seen during symptoms. Face of ashy pallor. Hands and feet cold. Forehead and palms moist with cold sweat. Pupils dilated. Pulse regular, 110. Blood pressure, 90/68. General appearance of shock. States that symptoms are often severe during night. Is afraid to continue at work or to go on street alone because of faintness and dizziness. Urinalysis: Sugar, 0.28 per cent. No albumen. No acidosis. Blood analysis:

¹ Calcium determinations were made by the technique of Kramer and Tisdall, Jour. Biol. Chem. 1921, XLVII, 475. Determinations of inorganic phosphorus were made by the method of Tisdall, Jour. Biol. Chem. 1922, L, 329.

* From the Los Angeles Metabolic Clinic. Preliminary Report.

Sugar, 138 mgs. Calcium, 7.2 mgs. Inorganic phosphorus, 3.33 mgs.

APRIL 13, 1924—Has been away from work for one month. Feels well. No symptoms for two weeks. Blood calcium, 12.6 mgs. Blood pressure, 136/80.

MAY 10, 1924—Patient has continued at work without symptoms.

1032 West Eighteenth Street.

DISCUSSION

F. R. NUZUM, M. D. (Santa Barbara Cottage Hospital, Santa Barbara)—Doctor Smith's report of a symptom complex in diabetes that might easily be confused with symptoms caused by insulin overdosage is a matter of great importance to those treating diabetic patients. He has shown that there is a difference in the symptomatology of the two conditions, and that laboratory studies will determine at once whether insulin overdosage is actually the cause of the condition. His studies having to do with calcium and inorganic phosphorus of the blood are interesting and suggestive. Further work will be necessary to determine what these findings signify.

A considerable number of diabetic patients with whom we have had to do have had complaints which are covered by the term "neuritis." Any or all of the extremities have been involved in many of these patients. As improvement occurs coincident with the use of insulin, a large per cent of them have become free of these "neuritic" pains. Some extremely emaciated patients, when gaining weight rapidly with the help of insulin, have complained of pains in the joints of the lower extremities upon first arising in the morning. This complaint is not to be confused with the "neuritis" complained of as noted above.

ALBERT H. ROWE, M. D. (242 Moss Avenue, Oakland, Calif.)—The syndrome which Smith reports has been noticed in a few of the patients I have under treatment with insulin, though any urgency in regard to such symptoms has not impressed me. I have carried out calcium determinations on some forty diabetics during the last year with the titration method of Clarke of the University of California. During the same time, in order to be sure of the normal variations obtained by this method, we have determined the calcium content of the blood plasma in fifty normals, most of whom were first and second year medical students. The results obtained in this normal series vary between about 8 milligrams and 12 milligrams per 100 cc. of blood plasma, and the diabetic values have fallen within the same range, excepting in several cases of coma where with much dehydration the calcium was around 13 or 14 milligrams. I am continuing the calcium studies, and it will be with added interest that I shall watch for the syndrome which Smith describes and seek to corroborate his findings in regard to the calcium values in the blood plasma of such patients.

P. BERMAN, M. D. (Los Angeles General Hospital, Los Angeles)—I have on several occasions observed a train of symptoms similar to those described by Smith, especially in patients taking large doses of insulin. The blood sugar examined at the time of the reaction does not show the expected hypoglycemia. This was especially noticed in some patients recovering from deep coma after very large doses of insulin were given. Pain in the extremities was a most usual symptom in my patients. The cause of this condition in several patients was considered to be due to the too rapid reduction in the blood sugar, though the level of the sugar in the blood still remained above normal.

The relation of this symptom complex to the calcium condition of the blood is certainly of great interest.

Do You Know Him?—A man who is now a prominent practicing physician was speaking of an old doctor who has just died. "I remember," he said, "when I was an interne, coming in late one night to the hospital and I saw this doctor sitting on the steps. 'What is the matter?' I asked him. 'Well, that woman we operated today,' he said, 'I went home and went to bed, but I kept thinking about her and I couldn't sleep, so I got up and dressed and came over. I thought it was better to be around here in case any complications should come up.'"—Missouri State Medical Journal.

RINGWORM OF THE SCALP *

By HIRAM E. MILLER, M. D., San Francisco

The disease increasing.

X-ray the best treatment and the quickest cure.

DISCUSSION by Samuel Ayres, Los Angeles; Granville MacGowan, Los Angeles; O. V. Schroeter, Los Angeles; Moses Scholtz, Los Angeles; Harry E. Alderson, San Francisco.

THE marked increase in the number of patients that I have recently seen with ringworm of the scalp has prompted me to bring this subject before you. In the last six months, I have treated in clinic and private practice over ten times as many cases as in any previous six-month period. The cases have been diffusely scattered throughout the San Francisco bay region, and are not the result of an epidemic in a single institution or localized community. I do not know the cause of this increase, but I think that it may go hand in hand with a general increased prevalence of ringworm infections of other parts of the body.

The following chart will show this increase:

1920	1921	1922	1923	1924	Total
- 3	3 6	6 4	3 19	43	87

Of the 19 cases in the last half of 1923, 18 occurred during November and December. All of the cases in 1924 have occurred during the last four months. This makes a total of 61 cases during the last six months. The largest number that I had seen in any previous six months was 6. Of these 87 cases, 19 came from private homes, and the remaining 68 from five different orphanages or institutions.

Before the advent of modern x-ray therapy, the treatment of this number of patients would have been a long and tedious process. I personally have not had any experience in treating ringworm of the scalp with local applications. At the Paris Ringworm School, prior to the time when x-ray therapy was used, it took, on an average, two years to cure their cases. This was under ideal conditions, the therapy being given by experienced attendants. Darier states that it takes an average of eighteen months to produce a cure, with a few taking from two to four years.

A few of my cases were well and back in school in a month. On an average, they were away from school for seven and one-half weeks, the longest period being three and one-fourth months. The hair had not returned in this time, but the child was cured of the ringworm infection.

I do not wish to advocate x-ray therapy for all cases of ringworm of the scalp, nor do I wish to deny the fact that isolated cases may be cured by local applications in a comparatively short time. Broadly speaking, however, I do think that x-ray therapy is the method of choice and the only type of therapy to be carried on in institutions on account of the danger of infection to others.

Ringworm of the scalp clears spontaneously at puberty, probably due to some inhibitory action of the glands of internal secretion on the growth of the organism in the hair shafts. Children who are 12 to 13 years of age may, therefore, be treated with local applications, knowing that they will clear

*From the Department of Dermatology, University of California Medical School.

No. 1—Complete defluvium due to x-ray therapy. Ringworm infection is cured and hair is returning. Photograph taken one month after treatment.

No. 2—Partial defluvium due to x-ray therapy. Hair has all fallen from ringworm areas. Disease cured and new hair coming in. Six weeks after treatment.

within a few months, due to internal changes. In an infant of six and one-half months, I was able to clear up the disease in a few weeks with local applications. In a child under 3 years of age it may be difficult to give x-ray therapy, as the little patient will be unable to stay quiet for a sufficient period of time. All patients between the ages of 3 and 12 can generally be treated with x-ray therapy without difficulty. I have had some children of 3 years of age that were much easier to treat than others of 8 or 10. Institutional children in general are ideal patients, while those from private homes are often spoiled and unruly.

It is needless to say that a positive diagnosis must be made before the patient is submitted to x-ray therapy. The main difficulty that one encounters is in differentiating the disease from alopecia areata. The bran-like scales, the stumps of hairs, and the localized areas of alopecia in a young subject are always more than suggestive. Microscopical examination of the stumps of hairs should always be done to make a positive diagnosis. The diagnosis should be made as soon as possible to prevent the possibility of infecting others.

When there is only one visible lesion, one may be tempted to epilate this area alone. In general, I think this is always unsatisfactory. When the clippers are run over the scalp, many smaller areas are found that could not be seen before the hair was clipped. If one area is to be treated, make that exposure correspond to one of the five Kienböck-Adamson areas, so if further treatment is necessary the other four areas may be used. I had one case referred to me on which the localized areas only had been treated, and many of the early areas were reinfected before the later ones were healed and a sufficient period of time had not elapsed to allow further x-ray treatment.

In 1897, two years after the discovery of x-rays, Freund suggested the use of x-ray in treating local-

ized areas of ringworm of the scalp. Due to inaccurate instruments, many cases of permanent alopecia resulted. In 1904 Sabouraud and Noiré introduced the plan of epilating the entire scalp at one sitting. In 1907 and 1909 Kienböck and Adamson, respectively, elaborated our present method of treating five areas. The advent of the Coolidge tube in 1914, the development of the interrupterless transformer by Snook in 1908, and the arithmetical method of computing dosage as advanced by MacKee, Remer, and Witherbee, have made x-ray treatment of ringworm of the scalp a safe procedure.

X-ray treatment for ringworm of the scalp is solely a mechanical process. The spores and mycelia are unaffected by the roentgen ray. The ray causes the hair shaft to fall from the hair follicle in from fifteen to twenty-one days after exposure. It thus removes the millions of spores and all of the hair in which they may live.

The local treatment that has been recently applied to the scalp may be a contra-indication to immediate radiation. If mercury, iodine, sulphur, chrysarobin, etc., has been applied in any form, a period of a week or ten days should be allowed to elapse before x-ray treatment is given.

The hair should be cut close to the scalp, to enable one to make careful measurements and to prevent it from acting as a filter.

I do not wish to go into the technique of x-ray treatment of ringworm of the scalp in detail. Anyone who endeavors to do this type of work should acquaint themselves with every detail as brought out in MacKee's text-book on "X-ray and Radium Treatment of Diseases of the Skin." The scalp is marked off into five areas, according to the Kienböck-Adamson method. One Holzknecht unit of unfiltered x-ray therapy at skin distance is given over each of these five areas at one sitting. The whole procedure is carried out in a period of twenty to thirty minutes. The hair falls out within two to

three weeks after treatment. With this technique, all of the hair may not fall. In general, the diseased hair falls first, and even with a partial defluvium the result will be satisfactory. The hair begins to return almost immediately, and the patient will have a good growth of hair in three or four months. The margin of safety is likely such that one may give 25 per cent more than this amount without disastrous results, but this should not be encroached upon.

Of the eighty-seven cases that I have treated with x-ray therapy, I have not had a single case with any permanent alopecia. Everyone should have the same results if they follow the technique carefully. In the first two patients that I treated, the hair did not fall at all. They were the first cases with ringworm of the scalp that I had treated with this machine, and they did not receive sufficient x-ray to cause a defluvium. They had to be retreated.

The after treatment of most of these cases is very simple. The children are provided with cloth caps, to be worn under the regular head covering. They have to be changed daily or bi-weekly, and boiled before reusing. These are discarded as soon as the hair has fallen. At the end of the second week I prescribe a 3 per cent ammoniate of mercury ointment to be massaged into the scalp, with the idea of preventing reinfection.

A week or ten days after the x-ray has been applied the areas may become inflamed. In certain cases (10 per cent) mild as well as severe toxic symptoms may develop along with a more or less severe impetiginized dermatitis of the entire scalp. Under the continued use of a 3 per cent ammoniate of mercury ointment, perhaps supplemented by boric acid compresses, the areas clear up in from ten days to two weeks' time, not however, without considerable worry and concern on the part of the parents of the child.

Without thorough study one cannot appreciate the economic and social aspects of the disease. Under modern x-ray therapy each patient generally remains out of school from six to nine weeks, and may have been the cause of several others remaining away for similar periods of time. If the disease is left untreated or treated with local applications alone, the child may be forced to remain out of school until the disease heals spontaneously at the age of puberty. He is then so backward that he may prefer to go to work rather than to school.

In conclusion, I wish to call your attention to the marked increase in the prevalence of ringworm of the scalp, to roentgen-ray therapy as the best and quickest way to a permanent cure and to the comparative safety of this procedure if all details of technique are carefully carried out.

Fitzhugh Building.

DISCUSSION

SAMUEL AYRES, JR., M. D. (Brockman Building, Los Angeles)—I thoroughly agree with Dr. Miller regarding the efficacy of x-ray in the treatment of ringworm of the scalp; its rapid and satisfactory results have been amply demonstrated. In the hands of such a capable operator as Miller it is reasonably safe. But I do contend that conservative measures are preferable in the average case.

The element of risk in roentgenotherapy cannot be entirely removed, and I do not feel that any element of risk whatsoever should enter into the treatment of a benign

condition when absolutely safe measures can be applied with success. In treating carcinoma or some serious disorder which threatens life, a reasonable element of risk is justifiable. A personal experience of my own in which I was very nearly responsible for producing a permanent alopecia has given me a wholesome respect for the possible dangers of roentgenotherapy. I am not nearly so pessimistic concerning the treatment of scalp ringworm by local applications. I thoroughly agree and insist that epilation shall be the first step in treatment, but with a little care and patience this can be accomplished in a most thorough manner by means of epilating forceps or in more extensive areas by the application and rapid removal of sheets of adhesive plaster after the hair has been cut close. The infected hairs readily adhere to the adhesive. Rigid cleanliness to avoid reinfection must be observed. A variety of local applications has been successful in my hands, especially sulphur and salicylic ointment. The treatment must be kept up from four to six weeks or longer, and epilation must be repeated every few days as needed. Thorough application of the medicament is necessary; it should be rubbed into the entire scalp for at least fifteen minutes every night and morning. Since many of our cases are seen at the Parent-Teachers' clinic and are under the careful supervision of school nurses, we feel that our cures are permanent in a high percentage of cases, and that they can be effected within a month or two. The large spore type of ringworm is often overlooked because it does not present the typical bald areas. School nurses especially should be taught to recognize these less typical cases which are often confused with seborrhea.

Although I have no available figures to offer, I have not been aware of any increase in the incidence of tinea capitis in Los Angeles.

GRANVILLE MACGOWAN, M. D. (Brack Shops Building, Los Angeles)—Dr. Miller has given to us a very interesting exposition of the most modern and rapidly successful method of treatment for ringworm of the scalp. No fault can be found with his statistics; nor are his claims unreasonable. It is alluring enough when we consider that we have at our command an agent that is clean, painless, and requires but one application to effect a cure of this loathsome disease within a very few weeks.

And yet I think I can easily see that its popularity will probably not be great, for unfortunately no one can say more than this skillful roentgeologist where he speaks of the "comparative safety of this procedure if all details of technique are carefully carried out."

There is always a chance that an undefendable suit for damages may be just back of its use, for an occasional destruction of the hair follicles and permanent baldness may result.

In private practice, given the proper attention by means of local remedies, the outlook for the care of ringworm of the scalp is only in the exceptional cases, the *bête noir* it is pictured in the books. It usually can be overcome in a reasonable time by skill applied with care.

Who of us would look with equanimity upon the unpleasant sight of a girlchild of our own made permanently bald so that she might be rid of a disease that, at the most, is only a nuisance.

O. V. SCHROETER, M. D. (Union Bank Building, Los Angeles)—Until such a time in dermatological practice as x-ray exposure to human tissues can be so precisely measured as to obviate all harmful results in all instances of average practice—and it is doubtful if such a time can ever come—especially in view of varying susceptibility as well as other factors, this form of treatment should not be the one of election. And such is the case in the treatment of ringworm of the scalp; the usual methods of treatment get results in even less time, in most cases, than it takes to recover from the x-ray alopecia when that is not permanent.

In fact, as with ringworm of the scalp, many cutaneous diseases, too many, are treated roentgenologically that should not be or could be treated with as good or better results by other methods. My experience is that the use of x-ray should be more restricted in the treatment of skin conditions. When one sees inflammatory skin conditions treated even by dermatologists in this way, it brings the thought that the x-ray is used many times because it is

handy, and the apparatus cost something, and not because the case was selected.

This is no criticism of the skillful epilation as done by Dr. Miller and others before him. The method should not be used generally.

MOSES SCHOLTZ, M. D. (Brockman Building, Los Angeles)—The advocacy of x-ray treatment as the method of choice in ringworm of the scalp can be accepted only with certain reservations. Theoretically, it must be granted that, in the hands of a competent operator, x-ray is the most effective, clean, quick, and reasonably safe method of treating ringworm of the scalp. However, I fear that, should we broadcast this notion and encourage the average regular and irregular practitioner to attempt this short cut to the cure of ringworm cases, disastrous results would follow. We see already entirely too many x-ray acute and chronic burns following the treatment of perfectly benign dermatologic conditions, such as psoriasis, eczemas, warts, etc. Epilation of the hair by x-ray is one of the most delicate technical problems in practical x-ray work, and should be entrusted only to men handling large numbers of these cases, specializing in this line of work. Leaving aside the question of idiosyncrasy, which is doubted by most roentgenologists, the milder degree of it—individual hypersensitiveness—cannot be denied; neither the possibility of a delayed x-ray reaction can be gainsaid.

I agree with the previous speaker that, in a benign condition, such as ringworm of the scalp, which in many cases responds to local medication, would be ill-advised to use as a routine measure a weapon potential of dangerous effects as x-ray. In my opinion, every case of ringworm of the scalp should be given a trial of thorough local medication for a reasonable period of time, say from four to six weeks. Only persistent, intractable cases, those generalized all over the scalp, also cases lacking facilities of proper nursing (which is the most important factor in the treatment of ringworm), and particularly institutional cases, should be referred for x-ray treatment. With this reservation of using x-ray only in certain types of cases as means of the last resort, and not as the method of choice, I fully endorse the advocacy of x-ray treatment in ringworm of the scalp.

HARRY E. ALDERSON, M. D. (240 Stockton Street, San Francisco)—I have read Miller's paper with much interest, for I know something about his good work.

Roentgen-ray treatment of this condition, according to MacKee's technique, is cleanly and effective. In the hands of a careful man like Miller it is safe, and the results are good. There are other effective methods, but they are useless unless the patient and family co-operate fully. Where x-ray treatment is not feasible, I use a prescription given me by Jackson some years ago, containing iodine crystals in goose grease, with which you are all familiar. I have found it satisfactory. Lately, I have been using also a penetrating cleansing lotion of iodine and carbon tetrachloride. The patient must carry out the treatment intelligently and faithfully.

We are seeing a great many cases of ringworm at the Stanford Skin Clinic (and they come from all over the city), but we have not noticed any very marked increase in their number. It seems to me that Miller's rate of increase may be due to the rapid growth of his practice rather than to other causes. There are some children's institutions that seem to be regular incubators for this sort of thing. We can trace many of our ringworm, impetigo, and scabies cases in children to those places. We can keep on treating these cases successfully, but until the foci that exist here and there are cleaned up, we shall continue having many new cases.

DOCTOR MILLER (closing)—In general, the discussion of this paper has brought out the facts that I wished to emphasize. X-ray therapy of ringworm of the scalp should not be attempted by those who are not thoroughly familiar with its use, especially in the treatment of this disease. I purposely omitted the details of technique, to prevent anyone from attempting to treat the disease with only the data from this brief paper.

I wish to take exception to the statements that most cases of ringworm of the scalp can be cured by local applications in a month or two, and that the disease at the most is only a nuisance. I do not believe that the authority that I quote as to the average duration of the disease can be questioned. Darier's statistics of thousands of cases that

were put into an institution and kept there until well show that it takes an average of eighteen months to produce a cure without x-ray therapy. They were treated by expert attendants. Some were well in a month or two, others took three or four years, the average being eighteen months. I know very well that some cases can be cured in a very few months without x-ray therapy. In private or clinic practice we follow those that clear up quickly, while those of long duration are apt to consult others, in the hopes of a more rapid cure. If a child is forced to remain away from school for six to eighteen months or longer, and if he has given the disease to others who had to lose their schooling for a similar period of time, I think that the disease is not a nuisance, but a calamity.

If a child with ringworm of the scalp can be given constant and intelligent nursing and kept isolated from other children, that child may be treated successfully and rather quickly cured without x-ray therapy. Unfortunately, most of the cases occur among the people in poor circumstances and large families or in institutions. These patients, I believe, should have modern x-ray therapy, in which minute care is given to all details of technique.

THE SURGICAL TREATMENT OF THE OBSTRUCTING PROSTATE *

By FLOYD F. HATCH, M. D., Salt Lake City, Utah
(From the Inter-Mountain Clinic, Salt Lake)

*Analysis of twenty-eight cases.
Study of recent literature.*

DISCUSSION by Mark Brown, Ogden, Utah; W. G. Schulte, Salt Lake City; James R. Dillon, San Francisco.

THE radical surgical procedures that we employ in prostatic obstruction must more than counterbalance in percentage of safety the dangers of chronic bladder residual with infection and mechanical obstruction to the outflow from the kidneys, resulting in their gradual destruction. In simple language the probability of "cure" must not be worse than the disease.

To appreciate exactly what we are offering to the public and justify ourselves in proceeding with certain types of surgery or medicine, we should periodically classify and study our treatment and results and then act on the basis of our own statistics, and not upon those of famed contemporaries. It was with this idea in mind that I have prepared an analysis of my last twenty-eight cases of prostatic obstruction that have had radical surgical treatment.

The pathology and mechanism of prostatic hypertrophy, according to some authorities, is that the prostate proper atrophies in advanced life, while the submucous glands undergo hypertrophy. These proliferating peri-urethral glands spread in various directions and thereby intrude upon the prostatic gland, which, in consequence, undergoes further atrophy. The prostate itself often appears as a pseudo-capsule, about half a centimeter thick, which the microscope will identify as prostatic tissue. The correct term should be nodular hyperplasia of the peri-urethral glands which are located between the verumontanum and internal sphincter. Predominance of adenomatous or fibromyomatous features are of no real importance, as there is no pure formation of either type. The so-called adenomatous type is observed in about 90 per cent of the cases, while the hard sclerosed nodules or fibrosis, constituting 10 per cent, are secondary to inflammation of the

* Read before the Salt Lake County Medical Society, April, 1924.

prostatic tissue. The hyperplastic process cannot be considered a pathologic process. It is no more a disease than gray hair. The expansion of the proliferating glands encounters several mechanical hindrances. Toward the perineum the diaphragmaurogenitale (triangular ligament) presents an insurmountable barrier. At the posterior surface the prostate is quite an important obstacle, more pronounced in some cases than others; the only direction of little resistance is towards the bladder. This direction is along the prostatic urethra, which, in order to keep pace with the proliferating glands, undergoes numerous changes in regard to size, lumen and curve. The glandular undergrowth, as will be seen, shows a tendency to elevate the floor of the bladder, either in toto or in segments, associated with the upward dislocation of the internal sphincter. The internal urethra undergoes stretching often from one to four centimeters and takes on distortion of normal curve and narrowing of the transverse diameter. Urethral muscles become distorted and lose power and tone to aid in sphincteric control.

As there are many cases of mild obstruction not necessitating other than temporizing methods, I will outline briefly what in my mind constitutes the necessity for prostatectomy. A clear indication is afforded when there are urgent signs pointing to interference with function of vital organs. Oddly enough, the most urgent indications often do not direct our attention to the bladder, as in "cachexia urinaria." These patients may complain only of loss of appetite, nausea, vomiting, and loss of weight. I consider the smallest residual indicating operation to be a few ounces if the urine is clear, and only a small definite residual if the urine is infected. Acute retention, in my experience, is not as grave an indication for operation as chronic retention. Bleeding is an indication for operation if profuse or if the bladder fills with clots or when less profuse or continuous if the blood loss weakens the patient. These indications are all relative and must be applied to suit the individual case. A good surgeon with low mortality may operate with less urgent indications than a surgeon with limited experience in these cases. Subjective symptoms referred to the bladder, as frequent, painful and difficult urination, are less urgent indications for operation than cases with renal embarrassment. Cases should be subjected to surgery when they interfere with activity or comfort to any great extent.

Prostatic obstruction to outflow of urine from the bladder, whether from median bar formation, contracted vesical neck, middle lobe hypertrophy or generalized enlargement from hyperplasia of periurethral glands within the prostate, constitutes pathology.

Clinically, prostatic obstruction must be differentiated from stricture, diverticulum and intra-prostatic polyp. Any of these cases may cause difficulty in diagnosis, which is easily settled by the cystoscope and cystogram.

The preliminary care of cases selected for operation consists, in the main, of rest, bladder drainage, building up of kidney function and general body resistance, as determined by renal function and blood chemistry tests and general clinical study. I am con-

vinced that many cases with only a trace of p. s. p. and a high blood urea test can, by persistent drainage and clinical treatment, be made fair operative risks, as I have found evidenced in my cases. Hugh H. Young, in a recent paper, reported results in ten cases of continuous catheter drainage in cases of low p. s. p. and high blood urea tests, raising p. s. p. from a trace to 60 per cent in some cases and lowering the blood urea test from 140 to 26. The longest interval of preliminary drainage in his series of cases was ninety-eight days, the shortest twenty-nine days.

I select the operation to suit the individual case, as the punch operation in cases without prostatic enlargement, but with true obstruction about the internal vesical orifice as diagnosed by cystoscope, as this is a relatively simple procedure. It gives perfect results in properly selected cases and eliminates the great hazard, pain and persecution of an unnecessary major operation. Most cases of the so-called small fibrous prostate should be treated by this type of operation, as most of the pathology centers about the vesical neck and the trauma of enucleation is out of proportion to the benefit derived. In these cases the floor of the bladder is smooth or concave downward rather than elevated with a resilient glandular tumor. If the case has not been previously cystoscoped, the surgeon who finds this condition before him does well to appreciate the situation and circumvent possible disaster by removing a generous notch of the contracted fibrous vesical orifice posteriorly, assuring himself of patency below by the passage of a sound. It may be repeated that this type of case could have more suitably been operated by the punch method if proper preliminary cystoscopic diagnosis had been made.

Prostatic obstruction includes carcinoma of the prostate, and though many early cases subside sufficiently with different methods of radium applications to the prostate, if the obstruction persists and the patient's condition justifies, a partial prostatectomy is appropriate to eliminate the obstructive factor, and then radiation should be continued vigorously often with exceedingly satisfactory results. Treatment in all cases of carcinoma of the prostate is coming to be more radical with early partial perineal prostatectomy and large amounts of radiation, sufficient to cause considerable slough, where the patient's general condition justifies.

In hyperplastic obstructions, I propose to remove the nodular hyperplasia in the manner least likely to jeopardize the life of the patient and to secure the best possible functional results with the smallest number of complications. In an early case with a clear urine and good renal function and normal blood urea test, I feel that an immediate one-stage operation is appropriate. If there are factors indicating prolonged obstruction with injury to the renal mechanism, I drain with an inlying soft rubber catheter, about No. 16 F. with two or three eyes near the tip, if tolerated well, until renal and blood tests appear sufficiently near normal or as near as it appears they will approach, and then do a one-stage supra-pubic operation.

One of the most valid arguments against routine preliminary cystostomy (realizing that much can be said for and against both of the usual preliminary

drainage procedures), is that an old man is put in a condition of enforced inactivity. Many are positively made bed-ridden, rather than being kept up and about in a high state of physical and mental tone, as is allowed by a well-tolerated inlying catheter, which is synonymous with encouraged daily out-of-door exercise and activity up to the day of operation.

By irrigating with weak mercoxyl solution or by administering acriflavine by mouth, it is demonstrable that the severe reaction from foul septic urine is almost entirely avoided as a post-operative complication.

In cases of mildly infected urinary tracts, I follow the above routine in general. Some very good surgeons go so far as to state that they feel infected cases treated with careful pre-operative measures are better risks than their preliminary clean cases. They state that infection seems to produce an auto-immunization.

Where there is severe bladder or renal sepsis or bladder stones present, I feel that a two-stage suprapubic operation is often indicated, and do the first stage under novocain anesthesia and drain the wound high so there will be sufficient room above the pubis to adequately enlarge the drainage wound downward at the second operation, obviating the danger of opening into the peritoneal cavity.

The preliminary procedure is prefaced by giving a hypodermic injection of $\frac{1}{4}$ grain of morphine sulphate one-half hour before trans-sacral anesthesia with 1 per cent novocain is administered. I have found that 5 minims of adrenalin chloride (1 to 1000 solution) gives additional duration to my bloc anesthesia and prevents untoward symptoms of mild novocain reaction due to too rapid absorption of the drug into the circulation.

Trans-sacral anesthesia, combined with abdominal wall field bloc, is one of the greatest adjuncts recently advanced tending toward the elimination of shock and aiding in improved technic of our prostate operative methods. Blood pressure apparatus and cardiac auscultation during recent cases using this form of anesthesia have frequently recorded no change in the patient's blood pressure and rate, rhythm or tone of the heart-beat or respiration change during the enucleation, where previously we expected blanching of the patient's face, rapid irregular pulse, enormous drop in blood pressure, and rapid labored respiration—all characteristic of marked shock during this part of the procedure.

Approximately one-half hour from the time of the sacral injection, my aim is to proceed with the cystotomy under local anesthesia, the bladder in the meantime having been gently distended with warm, sterile solution.

After opening the bladder, if the trigonal area and prostatic urethra are not anesthetic to pressure of the finger, I inject novocain directly into the base of the bladder and prostate. Then I proceed with the enucleation, using gas analgesia or not, as the patient desires. It is vital that this shock-producing procedure of enucleation be as rapidly accomplished as possible, not to exceed two or three minutes in cases where the trans-sacral anesthesia is not absolute. My dissection is begun by splitting the thin

portion of the prostate forward from within the urethra and dissecting backward and downward on either side from the cleavage plane so provided until the hyperplastic mass is freed and delivered from the cavity thus produced without injuring more than is absolutely necessary the floor of the bladder and the membranous urethra. Strong pressure or gouging with the finger to sever the lower prostatic urethra is often necessary.

It is startling at times to note the rapidity with which the prostatic tissue proper (musculo-glandular capsule) contracts down to close the operative cavity and how completely it controls hemorrhage, provided one has not torn across the trigonal area in the dissection. Visualization of the cavity must be sufficient to be assured of cessation of gross hemorrhage. Unusual hemorrhage not controlled by visual hemostasis indicates the use of one of the various hydrostatic bags.

Closure can be made rapidly in the customary fashion over a three-quarter inch rubber tube, two or three inches in length, adjusted so that it will not make pressure of any kind in the base of the bladder or prostatic cavity.

The normal physiology of the urinary tract usually irrigates the bladder sufficiently for the first few days to keep it reasonably free from stagnant septic material. In about forty-eight hours the large rubber hose drain is removed and the gentlest kind of irrigation is given daily with warm boric acid or mercoxyl solution from a slightly elevated container with soft rubber tube and catheter attached, the latter passed gently into the bladder an inch or two through the sinus. This procedure prevents collection of mucus and purulent digestive accumulation in the bottom of the bladder and prostatic cavity, which is absorbed to some extent and intoxicates the patient to the point of grave danger. This condition is often unrecognized, especially with those who are prejudiced against irrigating the bladder after operation, and the sepsis in the prostatic cavity rapidly evidences itself in the symptoms of anorexia, pallor, weakness, temperature, etc. I condemn early passage of catheter or instruments through the urethra or inlying catheter in these cases post-operatively.

It is well to be constantly on the watch for rectal impaction, a complication which patients appear to be particularly prone to develop following prostatectomy.

Dehydration positively must be avoided. Patients should have very large amounts of fluids to keep up kidney function and elimination under the strain of operative trauma, shock, and post-operative reaction. Dehydration kills more surgical patients than operative shock. Sufficient fluids should be given so that if the kidney cannot eliminate nitrogenous products in concentrated solution they will be forced to function by the very consequence of excessive dilution and excretion. Water should be given by mouth, rectum, hypodermoclysis, and, in case of urgent need, by the intravenous method, as much as 500 to 1000 cc. or more as often as indicated.

In excessive hemorrhage, patients should be typed early and transfused generously, as from this condition as from no other can the patient's vitality be

sapped insidiously until he is weakened and shocked beyond recovery, if neglected.

Operative trauma, hemorrhage, dehydration, and sepsis are our four great enemies in prostatic surgery. These complications must be avoided one by one as they appear by giving intensive attention and constant study to every detail of operative and post-operative treatment. Individualization of cases, as in no other group of maladies, is demanded, as well as constant care and attention of the surgeon to keep down to the reasonable limits of safety, a procedure that, with carelessness, readily approaches the mortality statistics of the not far distant past that are appalling.

CASE REPORTS

The twenty-eight cases of prostatic obstruction were operated by the supra-pubic method. Twenty-five were prepared for operation by urethral catheter drainage, three by preliminary cystostomy.

There was one death—case No. 22, giving a mortality of 3.5 per cent. This case was a male, aged 70, with a hyperplasia and some vesical neck obstruction. Preliminary care in the hospital covered nine days; post-operative care, seven days. On entrance the blood urea nitrogen was 33 mgms., at operation 24 mgms., and the p. s. p. test 46 per cent. The operation was done with local novocain and gas oxygen anesthesia. A moderate post-operative hemorrhage, for which a transfusion was done on the second day, was followed by symptoms of low-grade peritonitis and partial obstruction. Autopsy showed a very localized pelvic peritonitis, with no evidence of any site of entrance of infection.

The average age of the patients was 65 years. The shortest period of preliminary treatment was 4 days, and the longest 58 days; the average, 15 days. The shortest period of post-operative treatment before leaving hospital with wound healed was 16 days; the longest, 132 days; average, 31 days.

The clinical tests of urinalysis, blood urea nitrogen, p. s. p. test, white blood count, hemoglobin, and coagulation time were determined frequently during the preliminary treatment and before operation in all cases. These tests were continued until the patient was in suitable condition before operation was proceeded with.

The symptoms included polyuria and nocturia in the majority of patients, usually dating back for years. Microscopic hematuria was present in many of the infected cases. Gross bleeding from the urethra not accompanying act of micturition occurred in three cases from ulceration of mucous membrane of the intra-prostatic urethra from pressure of the hyperplastic nodule on the opposite side. Usually dysuria, retention, loss of weight or appetite, uremic symptoms or hematuria brought the case to the doctor for medical aid.

These cases were all cystoscoped and important preliminary data obtained regarding the presence of contracted vesical neck, diverticula or stones, and operation varied accordingly.

The anesthetic used in six cases was local novocain and ether analgesia during enucleation. Fourteen cases had local novocain and gas analgesia during enucleation. Eight cases were given trans-sacral and local abdominal field bloc, with four of these

given gas analgesia during enucleation at the request of the patient.

The complications were hemorrhage in two cases; epididinitis in three cases; vesiculitis in two cases; bronchitis in one case; peritonitis and intestinal obstruction in one case, and fecal impaction in two cases. The Hagner bag was used in two cases.

Twenty-seven cases left the hospital in good condition; three have since died, all more than a year after leaving the hospital—one of acute alcoholism, one of acute lymphatic leukemia, and one of recurrent carcinoma, which was operated and radiated and was improved with continence until his death two years after the operation from metastasis. One reports being in poor health, but apparently his urinary apparatus is not at fault. All the rest report that they are in good health and have no remarkable urinary tract symptoms. No case of incontinence was reported.

Coincident with this series, I treated two cases by the Young punch operation, with complete and immediate cessation of symptoms and recovery.

On the face of this report it would seem that this class of case has a high percentage of complications, but when one realizes that the subjects of this study are all old men, more or less broken in health and reduced in vitality, it seems remarkable that one can succeed with such a plan of action that the formidable operative care can be administered and such a low mortality rate be maintained in the presence of so many possible complicating factors.

Inter-Mountain Clinic.

DISCUSSION

MARK BROWN, M. D. (Eccles Building, Ogden, Utah)—This article is very thoroughly prepared, and Dr. Hatch is to be complimented. All his patients were operated by the suprapubic method of Squier. This seems to be the most popular operation used by urologists and especially by general surgeons. The only indication for the perineal route is in the case of the small contracted fibrous prostate or those suspected of new growth.

I watched Hugh Young do about fifty, and must admit that he stands supreme in the perineal method. In 1912 I watched Dr. Squier perfect his suprapubic method on cadavers, and would like to say the most important step in the enucleation of the prostate is to insert the finger into the urethra until you reach the "cut-off" muscle, then work in that region with your finger in the roof of the urethra, instead of the floor, until you perforate the urethra. Now enucleate from that laterally around to midline on one side, then the other, without injuring internal or external sphincters.

In the last two years I have treated five cases of obstructing prostate of the adenomatous type by the deep x-ray. All these patients had cystitis, night frequency and retarded flow. I find the relief of the patient's symptoms as good as with surgery, but the compensation is, as the New Yorker says, "not so good." I think the retention catheter is good; yet in the last year I have seen two patients die from apparent infection from the catheter before the prostate was removed. In post-operative cases, when the patient gets an alkaline bladder with crusts around the incision and in the bladder, I find that Horsford's acid phosphate by mouth and by mild irrigations to the bladder is very effective.

W. G. SCHULTE, M. D. (Boston Building, Salt Lake City, Utah)—Prostatic hypertrophy is a loose term as generally used, and includes all those cases that show evidence of enlargement of tissues surrounding the bladder neck. It is true that the prostatic tissue usually undergoes pressure atrophy, as the tumor, myoma or adenoma, encroaches upon it, and presses it against the dense prostatic capsule.

While enlargement of the prostate is commonly found

during the fifth and sixth decades, among men leading a normal sexual life, I should not go so far as Doctor Hatch and compare it to gray hair. In a personal communication, the late Dr. J. T. Geraghty made the statement that, in his experience, simple prostatic hypertrophy was unknown among men who had abstained from sexual intercourse, but that celibacy was no bar to cancer of the prostate. That corresponds with my experience.

The indications for operation are about the same as those usually mentioned, and will depend upon the whole picture rather than on any one symptom. The cystoscope, when it can be used, is a great help in diagnosis and in deciding upon treatment.

I think most operators are agreed that some cases are safe risks operated without a preliminary cystostomy. The blood chemistry seems to be of even greater importance in determining these cases than is the P. S. P. test. Local anesthesia is becoming more generally used, and the combination of sacral and para-sacral, together with cutaneous infiltration, gives brilliant results. However, I cannot agree that the routine use of epinephrin in the solution adds to the safety of the procedure.

Doctor Hatch's emphasis on dehydration is a good point. The tendency on the part of the nurse is to neglect the fluid intake. The operator must closely check the urinary output, particularly during the first three days after operation.

JAMES R. DILLON, M. D. (516 Sutter Street, San Francisco)—Doctor Hatch has very well covered the more important points regarding pathology, symptomatology, and preparation for prostatectomy.

The prognosis of the prostatic patient is proportional to the best management, just as the successful result is proportionate to the accurate diagnosis of the pathological condition present. Refinements in diagnosis and treatment have reduced the mortality and morbidity on this basis to a minimum, and further advance must lie in the education and conviction of the general practitioner and layman that the patient should seek earlier surgical treatment and not be allowed to drift into a dangerous condition beyond surgical aid by the use of urinary antiseptics and bladder drainage by catheter. Next important to establishing the functional stability of the kidneys in the preparation of the prostatic patient is the study of the cardio-vascular system. Myocarditis, often secondary to damaged kidneys and a forerunner of uremia, is a dangerous contra-indication to prostatectomy under general anesthesia. In these circumstances it should be done under spinal or para-sacral anesthesia, after thorough preliminary preparation of the heart and kidneys.

Regarding the choice of operative technique, we find 65 per cent of prostatic patients are excellent risks, and, if carefully prepared, have good surgery and are properly managed post-operatively, should recover, no matter whether suprapubic or perineal routes are used. With the 20 to 35 per cent of poor risks, it is better to do the perineal prostatectomy under gas and oxygen or spinal anesthesia, and get those decrepit old men about in a few days to avoid pulmonary, cardiac, and renal complications. The punch operation should be reserved for fibrotic contractures of the vesical orifice, or median bar obstruction, as hypertrophy of Albarrans' glands, and is usually indicated in the fourth decade of a man's life. After the age of 50 the fibrosis has extended through the prostate, obstructing the whole of the prostatic urethra, and nothing short of a prostatectomy will give complete relief.

Suggesting a Revival of Medical Apprenticeships—
 "The old system of medical apprenticeship had many things to commend it, but it is out of date and cannot be adjusted to the needs of the times," according to E. H. Ochsner (American Medicine). "There is, however, a real need for a system of apprenticeship and junior partnership which only the organized medical profession as a whole can work out and make operative. Such a system should utilize the vast practical experience and ripe judgment of the older members of the profession and the better technical training of the men just entering the profession and could be made equally advantageous to both, as well as the public in general."

COEXISTING LARGE FIBROID AND PREGNANCY—CAESAREAN SECTION AND HYSTERECTOMY AT TERM.

REPORT OF A CASE

By C. A. DELANCEY, M. D., San Anselmo, Calif.

This rather unusual case record is published, not only because it has interesting features, but particularly because of the "wild" stories about it published in some newspapers, and its treatment in the alleged "humor column" of a medical journal.—EDITOR.

MRS. X presented herself for examination because of digestive disturbances of two weeks' duration. She complained of nausea and distress at sight of food, particularly in the morning.

Further history revealed that she had missed her last menstrual period on March 4, 1924, although she had previously menstruated normally. She gave her age as 42, had been married ten years and had had no previous pregnancies.

Physical examination was negative except that a large solid tumor mass extending from within the pelvis to the umbilicus was outlined. It was about the size of a six months' pregnant uterus. Questioning revealed that this mass had been diagnosed four years previously as a fibroid tumor by physicians who had advised operation. The patient, because of her desire for offspring, had refused surgical intervention.

On September 3, 1924, the patient called again, stating that she had not menstruated since March and thought she had felt life in her abdomen in July. Examination at this time revealed a soft cervix, bluish external genitals and the mass greatly increased in size, and of soft consistency. The solid mass was felt to the right and lower part of the abdomen, while to the left and lower the mass was softer. Auscultation revealed a uterine souffle and foetal heart sounds in the lower left quadrant. A diagnosis of a five months' pregnancy, complicated by a fibroid, was made at this time.

The patient's period of gestation was uneventful except for a slight nausea which she complained of during the early months. As the tumor rendered a normal delivery impossible, it was decided to perform a Caesarian section *at term*.

On December 8, the patient was admitted to the hospital and on the following day the operation was performed. A left rectus incision was made and the uterus exposed. This was incised over its thinnest portion and a normal seven-pound girl delivered. The large tumor mass, together with the uterus with which it was intimately incorporated, was removed. The accompanying picture shows the specimen.

Dr. F. E. Blaisdell, who examined the specimen, reports it as a post-partum uterus, measuring 18 cm. in length, 19.5 cm. in width, and 10 cm. in antero-posterior diameter. Anterior surface presents a Caesarian incision sinistral to center, which measures 9 cm. in length. On posterior surface, likewise, sinistral in position is seen a circumscribed tumor measuring 3 x 4 x 4.8 cm.; it projects 1.5 cm. above the surface. Midfrontal section of uterus shows a large

Post-partum uterus with Caesarean scar and large fibroid.

oval solid elastic well-described tumor measuring 12.5 x 18.5 cm. in diameters. It is intramural in position, as its outer surface is invested by a thin, compressed layer of uterine tissue, and the serosa and subserosa is distinctly recognizable external to it. The tumor is in the right uterine wall. The uterine cavity is 11 cm. in length. The left uterine wall is 7.5 cm. in thickness. Cut surface of tumor shows pearly white strands of tissue running and intertwining in all directions; in scattered or continuous areas a large amount of mucinous substance is found. The tumor cut with marked resistance. The smaller tumor shows a similar structure, except that it is subserous and contains no mucinous material, and is entirely independent of the larger one. Microscopical examination of frozen sections mounted in balsam shows: The general histological characteristics of a fibroid. Scattered through the tissue are seen groups of epithelial cells arranged in the form of glands. There is mucinous softening, and spaces varying in size are filled with the mucinous material (gelatinous after fixation). No mitotic figures have been seen. In small areas near surface, groups of round cells and leucocytes are seen. Tumors are well-defined and apparently benign. Diagnosis: Adenofibro-myoma (intramural). Small fibromyomas (subserous).

The interesting features of the case are the normal, full-term development of the fetus in a fibroid uterus: Patient ten years married without previous pregnancy; conception at the age of 42; excellent recovery of both mother and child, following Caesarean and hysterectomy; absence of hemorrhage during gestation; justification for hysterectomy at the age of 42; complete preponderance of fibroid over uterus.

TREATMENT OF FRACTURE OF THE NECK OF THE FEMUR

By ETHAN H. SMITH, M. D., *San Francisco*

I SHALL not go into any unnecessary description of the hip-joint, or the various methods of treating the above-mentioned fracture. One method alone will suffice for nearly all cases, if properly applied.

As soon as I mention the method, I can hear many of my confreres say, "That is old." The main features of the method are old. So is the discovery of the circulation of blood. So also is the sunshine old, but it is still good.

Weight and pulleys in the straight position, with sand bags of the proper dimensions, properly applied, give ideal results, which are unequaled or unexcelled by any other method.

This method can be applied by a doctor all alone, anywhere that he happens to come to a patient, if necessity compels. Of course, the ideal place is to have the patient in a modern hospital. I would not think of treating a patient elsewhere, unless positively obliged to do so by force of circumstances.

The bed should have some thin boards placed under the mattress and over the springs from the level of the patient's shoulder blades to the feet. These boards should not impinge on the side rails of the bed, and should cover the springs only. The boards off an orange-box would do admirably. An anesthetic is never necessary. This fracture can be properly reduced and dressed without any unreasonable pain to the patient. Anesthetics cause a large number of fatalities in elderly people. If there were no other reason to recommend this method above all others, the avoidance of an anesthetic is ample reason why it is better than any other method.

The lower extremity is put in a straight position. A good quality of real moleskin plaster must be used.

Use two thicknesses of plaster. Have the strips five to six inches wide at the top, tapering down to three inches at the foot. Notch the margins of the plaster so that it will fit without wrinkles over the thigh, knee, and leg. Bandage the foot *always*. Use flannelette bandages, two and one-half inches wide and six yards long. After applying the plaster, be sure that it projects below the foot fully five inches. Make two holes in each lower end of the plaster, into which button a spreader, forked at each end, so as to button into the plaster. Having the two prongs to button into the plaster prevents the plaster from wrinkling and making sores on the leg. To this attach a cord with from fifteen to eighteen pounds in the adult. Excessive weight will defeat the purpose for which it is applied, by causing muscular spasm, and affords great discomfort to the patient.

Next have the sand bags ready—one 5½ inches in diameter by 4 feet in length, and another 5½ inches by 3 feet in length. Two smaller sand bags, each 4 inches in diameter by 2 feet in length, and one small sand bag 5 inches wide, 3 inches thick, and 10 inches long. Have an assistant grasp the ankle and make traction while the surgeon places his hand behind the trochanter major. While the assistant gently rotates the foot and leg inward, the surgeon

lifts the trochanter forward, and places the smallest sand bag behind the trochanter.

This feature of the dressing is the new feature in comparison with the rest of the dressing. The lack of the sand bag behind the trochanter was the one weak spot in this dressing during all the years it was in use. About fifteen years ago I began using the small sand bag behind the trochanter. It gives ideal results. After placing the small sand bag behind the trochanter, the longest sand bag is placed beside the patient's hip from the waist down to below the foot. The next largest sand bag is placed on the inner side of the thigh and leg. (I omitted to mention that the thigh and the leg are laid on a pillow placed lengthwise from just above the heel to above the knee, so as to prevent pressure of the heel on the mattress. This pillow is brought up around the knee and leg, and the sand bag is placed outside of it. Then two small sand bags are placed one on either side of the knee, the middle of each sand bag being just about opposite the patella. The upper end of the large sand bag is fastened to the pelvis by means of a binder going around the patient's hips, and around the end of the sand bag. Pads are put in over the bony prominences wherever needed. Then the two large sand bags are tied by means of a strip of bandage around the upper third of the thigh, another strip just above the knee, a third just below the knee, and a fourth a few inches above the ankle.)

The patient's body can be raised and lowered without interfering a particle with the fracture. The patient can be placed in almost a half-sitting posture, thus giving relief to the pulmonary circulation. That is vastly more comfortable than any other dressing, fulfills every requirement, and is the safest dressing in use today.

Necessity for operation very rarely occurs in fracture of the neck of the femur.

Flood Building.

Significant Extracts From Letters

"We were looking forward to a new baby due to be born in February. My wife died last August. We are still receiving letters from two sources full of optimism and advice about baby clothes and other matters. What can I do to stop these grief-renewing epistles?"

"Dear Better Health Editor—What can a grief-stricken mother do to stop monthly letters of advice about what to do for my baby, originally expected this month, but which I lost two months ago?"

"Dear Better Health—I am expecting my baby in March. The lady specialist at the — Health Center has been telling me what to do and what to eat. One day, not very long ago, I felt very badly and the health center was not open. I went to see Doctor —, who told me my urine was very bad and my blood pressure 185. He said I needed better care than I had been having. Whom shall I believe?"

The Written Word Is the Doctor's Permanent Background—"Whatever work we may do, either clinical or investigative, it will do little general good and will lose much or almost all of its effect unless the noteworthy part of it is promptly and well reported in the medical press, which itself indeed cannot grow and prosper unless the profession gives it the material by which it can live and grow.—Charles L. Minor, M.D. (Southern Medical Journal).

EDITORIALS

LEGISLATION AND HEALTH

The California legislature now in session has before it some 2000 bills, of which more than 10 per cent are about health. Some of these laws are constructive, others are of indifferent value, and too many are destructive and some even vicious in their bearing upon health and welfare. The League for the Conservation of Public Health has examined these laws from the standpoint of their health value and has prepared a digest of some 100 of the more important of them.

This review is based upon the laws as first printed, bearing in mind that most of them will be more or less amended before they came to a vote. The review is published in full in the March issue (February 20) of BETTER HEALTH, and several of the more important laws are discussed editorially in the same issue. BETTER HEALTH of the April and May issues will continue the comment upon the doings of the legislature, and in the issues following the adjournment of the legislature will analyze the health laws that come out of the "hopper."

Readers of CALIFORNIA AND WESTERN MEDICINE who are interested in legislative matters are invited to send comments and suggestions to the League office. Copies of telegrams, letters, and personal advice given to members of the legislature will also be of assistance in legislative publicity.

OLD AGE AT ITS BEST

The widely known and much-beloved physician, Doctor W. W. Keen, passed his eighty-eighth milestone on January 19. "Young men shall dream dreams and old men shall see visions," says the Holy Word. Doctor Keen is not only seeing visions, but he is interpreting them in language that travels round the world. We catch a glimpse of a vision in his "The Ministry of the Biological Sciences" published recently, the opening and closing paragraphs of which read:

"The more the religious man, and especially the clergyman, knows of science, the broader becomes his vision. Through study of the heavens above by the telescope and the spectroscope; and of the earth beneath by geology, chemistry, physics, etc.; and of the inhabitants thereof by anthropology, archeology, biology and other sciences, the wider becomes his horizon. These sciences deal with the works of God and, rightly interpreted, they must agree with the message of God in the Bible (also rightly interpreted), for both have a common origin—Almighty God. Any clashing of these views must depend on partial knowledge, i. e., on our ignorance of much as yet undiscovered, either in the Bible or in Nature, or on a misinterpretation of either. That we have learned so much is a happy augury for future wider and profounder knowledge.

"Revealed religion links itself with biology, and proclaims the blissful certainty of the Immortal Life through the incarnation and the atoning death of our

Lord Jesus Christ, our Blessed Saviour, the divine Son of the ever-living God."

We get another glance of one of the visions of this great Christian physician in his article on "Freeing Mankind From Disease" (Collier's, November 8, 1924), in which after a concise summing up of what has been accomplished in health progress, he says:

"And we are advancing toward even more wonderful things. When it will come no man knows; but of one thing I am certain: the day is sure to dawn, when, after thousands of years of bondage, mankind will be emancipated from cancer and many other diseases."

THE FIFTY-FIFTY BUBBLE

President Coolidge has effectively exploded what is known in Congress as the fifty-fifty appropriations bubble. This "movement," now costing in excess of \$100,000,000 a year, was just getting started. "I am convinced," says our President, "that the broadening of this field of activity is detrimental both to federal and state governments. Efficiency of federal operations is impaired as their scope is unduly enlarged. Efficiency of state governments is impaired as they relinquish and turn over to the federal government responsibilities which are rightfully theirs. I am opposed to any expansion of these subsidies. MY CONVICTION IS THAT THEY CAN BE CURTAILED WITH BENEFIT TO BOTH THE FEDERAL AND STATE GOVERNMENTS."

Under this pernicious scheme congress appropriates funds to the states, and says to them in effect:

"You can have this \$100,000,000 if you also will appropriate another \$100,000,000 and use it as certain federal officials in Washington tell you to use it; but it must be used strictly in accordance with instructions from Washington and under Washington supervision."

Of all these sinister measures, what is now widely spoken of colloquially as the Sheppard-Towner bribe, is the least excusable and most mischievous. It was once popular with certain people, but never at any time had the substantial support necessary for the sustained promotion of health progress. Most of its one-time advocates now speak of it apologetically, and since the President's definite stand has been so widely and generally endorsed, Sheppard-Towners are hard to find. Several states never have accepted the provisions of the "subsidy" law. The reasons for refusal to accept its provisions have been well summed up by Governor Baxter of Maine, who said in a much-quoted statement:

"I protest against the Sheppard-Towner bill: Because it is an unwarranted invasion by the federal government of the sovereign rights of the state of Maine; because it establishes in Washington a federal bureaucracy that is not likely to be in sympathy with the government of this state and the citizens thereof; because it *invades the privacy* of our homes; because it infers that the state of Maine cannot and will not properly care for those of its mothers and children who need assistance; because it pauperizes our state."

Where Congress Gets the Money—Financial agents of state after state are now pointing out the

fact the fifty-fifty "Federal Subsidy Funds," or "bribe funds," as many designate them, are obtained in the first instance from the taxpayers, and that *only a portion of the money collected* ever finds its way back to the state that collected it. California is among the states that suffer the greatest loss between the amount of taxes paid to the federal government and the fifty-fifty returns. This has been repeatedly published in the press of the state.

The Operation of the Law—Of course, it is the principle rather than the amount of money involved that is most widely condemned, but there are some interesting, some humorous and some pathetic incidents connected with the enforcement of these fifty-fifty laws—and particularly of the Sheppard-Towner one—which has proved to be the straw that broke the fifty-fifty camel's back.

OBLIQUE ADVERTISING

This term needs no definition. It was the subject of serious discussion at the recent meeting of the British Medical Association in connection with the report of the Central Committee on Ethics. The report of the committee states that:

"During the past few years there have been brought to the attention of this committee certain journalistic developments which seem likely, if unchecked, seriously to undermine some of the most cherished traditions associated with medical practice, and to lower the reputation of the profession among the more thoughtful sections of the community."

Some abstracts of the various rulings of the association upon the various phases of oblique advertising are deserving of thoughtful consideration by all physicians:

Referring to the subtle and indirect method of giving publicity to certain medical practitioners through the public press, sometimes without and sometimes with the active consent of those referred to, the British Medical Association issued the following warning to their members:

"The practices by a member.

"(a) Of advertising, whether directly or indirectly, for the purpose of obtaining patients or promoting his own professional advantage; or, for any such purpose, or procuring or sanctioning or acquiescing in the publication of notices commending or directing attention to the practitioner's professional skill, knowledge, services, or qualifications, or depreciating those of others; or of being associated with or employed by those who procure or sanction such advertising or publication, and

"(b) Of canvassing or employing any agent or canvasser for the purpose of obtaining patients; or of sanctioning or being associated with or employed by those who sanction such employment; are in the opinion of the council contrary to the public interest and discreditable to the profession of medicine, and any member who resorts to any such practice renders himself liable on proof of facts to have his name erased from the Medical Register."

In discussing the whole question of oblique advertising and the action of the association, the *Lancet* says: "Examples of the newer methods are to be found in interviews granted to newspaper representatives, and in signed letters or articles sent to newspapers. In many of these, members of the profession, either by direct assertion of the journalists concerned, or by more indirect methods, are referred to as possessing, or allow it to be inferred from

their own words that they possess, methods of treatment superior to those practiced by others.

"It is the recognized duty and right of a medical man to take his share as a citizen in public life, but there is no reason why this should involve any advertisement of himself as a doctor, and, with due care, improper advertisement can be avoided.

"Publicity is rightly allowed to medical men not in actual practice of their profession, since they cannot be regarded as using this publicity for the purpose of promoting their own professional advantage, and in view of the official position of medical officers of health and other medical men who hold posts in either the public health or other public service, publicity is sometimes not only permissible but necessary for the fulfillment of their official duty. The presumption in all these cases is that publicity is not sought for the individual's own gain, though it is possible that the practice might be abused and the presumption therefore fail.

"The publication of books and the delivery of lectures on semi-medical topics which are of general public interest and require medical knowledge for their proper presentation have been recognized as legitimate, subject to the avoidance of methods which tend to the personal professional advantage of their authors. There are many things innocent in themselves which may, by the manner and frequency of their doing, gravely contravene the principle that medical practitioners should not advertise.

"Speaking generally, it may be said that the medical men most often quoted in the press are not those whose opinions carry most weight with the medical profession or with the educated public. It is natural that those whom the press representatives most eagerly seek to draw into their service and utilize for their own advantage are those who have some recognized position or well-sounding address or title. It is, therefore, especially important that a stand should be made by such practitioners, who perhaps do not realize that the example set by them may well be pleaded in justification by those in a less prominent position.

"The Association is convinced that, in taking up an attitude of determined opposition to these undesirable journalistic methods, the Association is acting in the best interests of the public as well as of the medical profession.

"The extension of the advertising habit among the profession in general would certainly destroy those traditions of dignity and self-respect which have helped to give the British medical profession its present high status, and would gravely undermine the amenities and harmonious working of medical practice.

"If only those whose reputation is mainly derived from the newspapers allow their names and opinions to be quoted or to appear as those of 'the eminent' physician, surgeon, or specialist, the practice will die a natural death."

SOMETHING TO THINK ABOUT

AN EDITORIAL CHAT WITH PHYSICIANS
ABOUT AUTHORSHIP

In speaking on medical publicity before the Kings County Medical Society of Brooklyn, Arthur Brisbane (Long Island Medical Journal) stated:

"Medical knowledge and publicity are to human life what knowledge of engineering is to the machine, or the knowledge of mechanics to his automobile. . . . The problem is to get the information you possess into the minds of the more simple. . . . Remember, *repetition is reputation*. What we hear over and over we know. I think in that way (short daily articles) you could solve the problem you put before me of medical publicity. . . . After all, every man is glad to give information. . . . I shall be very glad to co-operate (in medical publicity) and I have considerable publicity with which to do it. I may have to do it on a small scale as regards space, but the smaller the space the better. *If you can express yourself in a few lines, everybody will read your message, while if you put it in ten columns, not one in ten thousand will read it.*" Thus speaks one of the most experienced, highest paid and most widely read authors in the world.

Whether we believe what Brisbane says about many things or not is irrelevant. What does matter, and what we as physicians in particular may learn from Brisbane and numerous other widely read authors is, that "brevity" is still "the soul of wit."

Physicians are among the oldest and most prolific writers, and yet we appear to be slowest in learning the most important lesson of successful writing—brevity. Yet, as *readers*, the lesson is before us all the time. As readers we follow precisely the same instincts that govern other people: *we shun the long article*. Rather than wade through thousands of words to find something worth while, even in an article on an important subject by a well-known authority, we lay it aside and wait until someone has prepared a brief abstract and read that. No physician, even one who does nothing else, can do otherwise and keep abreast with medical news. This fact explains the growing number of successful businesses devoting all of their time to abstracting medical literature for their subscribers.

Should this not teach us a lesson? Every medical author writes from legitimate and commendable motives: The desire to contribute something to medical knowledge; the desire to be the contributor and the desire to extend his personal reputation among his colleagues. These are precisely the motivating influences of all writers, the only difference being that, in all other fields, the author also depends upon the income from his writings for a livelihood. Surely, our commendable motives for writing should be important enough to induce us to recognize and adopt the methods that make for success in authorship in other fields.

This most of us do not do. We are learning, but we must learn faster and more universally. Medical journals should be as interesting to physicians and others working in the broad field of medicine and health as are public magazines in their fields.

To bring this about requires that authors should give the same serious study to their written words that they do in their methods with patients. In the latter, they strive for the simplest, most direct methods, and the utilization of the smallest possible amount of the time of patients consistent with thoroughness. Interesting style, consistency, conciseness,

brevity are even more important to a medical author.

Progress in medical authorship is encouraging. It has moved faster during the past few years than in previous generations. The motivating influence is the growing invasion of the field of medical writing for public readers.

During the several years that medicine and health education publicity has been carried forward by physicians in California, through Better Health magazine and the San Francisco Examiner Better Health services, there has been a noticeable improvement in the writing of hundreds of physicians. We all frankly admit that it requires more effort to prepare a successful message for popular readers than it does for medical readers.

So it *does*, but *should* it? After all, the fundamental requirements for success are precisely the same.

SHALL WE HAVE TWO MEDICAL PROFESSIONS?

Shall PERSONAL HEALTH PHYSICIANS and PUBLIC HEALTH PHYSICIANS be developed into two separate professions or shall *public health practice* be continued as a *specialty of medicine*—as it always has been—constitutes one of the very important health progress problems.

It is everyone's problem, and it will be solved. As a matter of fact, it is moving toward solution constantly. What that solution may be cannot be predicted at present. But we can look dispassionately at the forces tending to influence the final solution and thus determine our duties and responsibilities as physicians and citizens.

Certainly, the larger majority of those physicians who consider their attainments as assets to be used primarily and with reasonable unselfishness in improving the general health welfare of humanity believe that *public health practice* should constitute a specialty of general medicine practice. On the other hand, a minority of physicians supported and largely led by great non-medical organizations and wealthy foundations are out definitely and openly to *split medicine into two separate professions*.

There is more propaganda given out under the guise of informative publicity supporting such a division than upon any other single phase of health. The burden of most of the arguments is to the effect that the seven years of special education above high school required of all Doctors of Medicine, while it prepares them to practice *personal* health medicine, does not prepare them to practice *public* health medicine. They argue that a few weeks or months extra study, usually in specially designated schools, does prepare the personal health physician to practice public health, medicine, and that even a much shorter course in certain schools will prepare students, *not medically educated*, to practice public health medicine. Or, in the parlance of the propagandists, it prepares these non-medically educated persons to become "efficient health officers."

Nor is this the whole aim of those promoting the idea of two separate and distinct medical professions. During the last year in *official* government documents and reports of voluntary organizations, the announcement has been frequently made that public

health medicine included personal health practice—"preventative AND CURATIVE."

This serious move concerns all people, and it is being actively promoted by powerful influences. In claiming broadly for everyone to read, that the education of a Doctor of Medicine "does not fit the physician to practice public health medicine," these propagandists are thus encouraging the non-medical public to arrive at the logical conclusion that if such a physician is incapable of serving the public health he must also be incapable of serving the family or individual health requirements.

WHAT ARE THE FACTS?

Out of over 3000 counties and over 6000 cities and municipalities in the United States, there are less than 500 that engage the full time of even an educated licensed physician "health officer."

We would like to suggest to these propagandists that before they criticize the educated physician too strongly as being incapable of doing for the *public* health what he is doing for *personal* health they get rid of the quacks and other incompetent "health officers" that have not even a medical education and who now hold authority in hundreds of places.

It also is appropriate to call their attention to the bad taste and perfidy of criticizing the thousands of educated physicians who are carrying on public health duties for the vast majority of our people in most places for a pittance of from \$5 to \$25 per month.

If there is not money to pay even the alleged incompetent doctor of personal health medicine enough to buy gasoline with, how do they expect to pay their specially and superiorly educated doctor of public health medicine to devote all of his time to such work?

Every educated physician endorses the idea of special education for specialists. This whether the specialty is surgery, obstetrics, or public health. *But the public welfare and the public health is not advanced by trying to reach an ideal by destroying what we have.*

The worthwhile public health physician still considers himself as much a part of the medical profession as does the surgeon, the obstetrician, or any of the other several specialists of a great profession.

MORE ABOUT FEE SCHEDULES

In commenting editorially upon the controversy which grew out of the fee schedule adopted by the District of Columbia Medical Society still going on in the public press, the Texas Journal of Medicine believes:

"The issue is whether doctors have a right to agree on the value of a service which even the most violent dissenter must recognize as strictly personal, and one involving both knowledge and skill."

The Dallas News, in criticizing doctors' fee schedules, editorially urges: "If the musician had to sing for his audience one at a time, his prices would be much higher, and his services would then be rendered under comparatively the same conditions as physicians who render individual service."

The threat is also made in this and other newspaper editorials over the country that, unless doctors

pause in this "unionized labor" method of "price fixing" and "working conditions," the public will force "open shop" methods through "collective service enterprises," such as "health insurance," "clinics," "health centers," and what not.

"The Dallas Chronicle agrees that doctors have the same right to fix their fees, a practice usually granted to plumbers and carpenters, and concedes that the doctor is just as necessary to the health of the community as the plumber."

Press clippings indicate an astounding public interest in doctors' "fee schedules," and at the same time a remarkable variety of opinions as to what should and should not be done. So extensive and energetic has been the nationwide reaction to the Washington doctors' fee schedule, that medical leaders would do well to restudy the problem. As stated in our last month's notices, papers in general sympathetic to organized labor practically all endorse the doctors' action and some predict that the next step will be affiliative with the A. F. of L. Other papers, for the most part, criticize the doctors and many of them are bitter in their denunciation. A substantial number of editors point out that it is actions of this sort that makes friends for those who are out to make personal and public health a "public utility" either operated by the state as education now is or operated by great corporations under state supervision. *It is pointed out that doctors appear to be blind to the progress being made in both these directions.*

Of course, most thinking physicians are not "blind" to either what is being done, who is doing it, nor to the plans that are still, for the most part, in the chrysalis stage. The trouble is that doctors are not really organized and there is little to indicate that they can be organized so as to do effective team work. This may or may not be a fault, but in any event it is a fact. It is largely explained by the fact that doctors, by education and in their life's work, are individualists. Their work is highly personal and they are thus personally competitive in the best meaning of that word. The nature of their service is calculated to make dictators out of them, and, as a matter of fact, every doctor, whether he appreciates the fact or not, becomes a benevolent dictator to his clients. It could not well be otherwise—nor should it. However, this spirit so essential in his life's work is calculated to make of him a "bad risk" as an organization man. In the aggregate, he is fine as a leader—when he has time—but he is not strong in accepting the reins of organization, however gently pulled by leaders of his own choice in his own organization, working to uphold and strengthen the cause he serves. In other words, he is a poor private, but a splendid and much-loved captain of those he serves.

We see the results quite clearly in any discussion of "fee schedules" and it is, of course, equally clearly demonstrated with almost any other question that requires both leaders and followers to carry out as a "team measure." *There is not now and never has been an effective "fee schedule" in any county, city or other community.* Only from 30 to 60 per cent of the physicians of the various communities are even members of their medical societies to start with, and

no "fee schedule" has yet been devised and made effective for all of those who are members, to say nothing of the others.

A percentage, not by any means small, of physicians believe that *a personal fee schedule is an essential and indissoluble part of the personal service that physicians render to their patients and clients.*

There are some tens of thousands of physicians who earn their livelihoods from salaries and by other methods and are not interested in fee schedules. Then there are many, many doctors who do their work under forms of commissions, so much per person per month, or so much per unit of service, all being fixed and managed by government, other employers, insurance carriers, officers of organizations or what not, and in no instance subject to control by physicians either individually or collectively.

These are only a few of the many reasons why we, as physicians, ought to rehearse several things pretty extensively among ourselves before we tackle the big Berthas of business and organization on the one hand, and the emotional, uncertain and fickle jade, public opinion, on the other, with important matters of organization policy and public welfare.

LEAD POISONING FROM ETHYL GASOLINE

Probably no other metal is used in so many different forms and on so vast a scale as is lead. The result is that actual and potential poisoning from lead is greater than from any other metal. It is greater today than at any previous time in the history of civilization. Various aspects of lead poisoning were discussed in a symposium before the Section of Pharmacology and Therapeutics of the American Medical Association in Chicago last June and also previously in these columns. These discussions leave the impression that much still remains to be learned about the nature and the treatment of lead poisoning. Until recently very little has been said about possible poisoning from the organic compound, lead tetraethyl, in its new rôle.

Lead tetraethyl is being used extensively as a constituent of "ethyl gasoline" and of various trademarked "anti-knock" mixtures. According to a recent investigation of the Bureau of Mines of the Department of the Interior in Pittsburgh, Pa., "ethyl gasoline" is ordinary motor gasoline to which has been added about 0.04 per cent of lead tetraethyl and 0.06 per cent ethylene dibromide by volume. The object of the lead tetraethyl is to eliminate the detonation or "knock" in internal combustion engines, thereby increasing the economy of fuel consumption and the mileage per gallon of gasoline and permitting the designing of more efficient engines. During combustion, the lead tetraethyl is converted in the presence of a halogen carrier, ethylene dibromide or trichlorethylene, to lead bromide or chloride, which is non-volatile, insoluble, and mostly deposited in the engine head and exhaust pipe in the form of scale or white deposit. The remainder is discharged with the exhaust gases, the larger particles falling to the floor or street, and the very small ones (approximately the size of smoke particles) remain suspended in the air. In addition, a good deal of the lead forms a sulphate, the sulphur coming from the

gasoline; some occurs as oxide, and a small amount as metallic lead. Hence, there is a possibility of lead poisoning from inhalation of atmosphere containing the exhaust gases. Another possibility is from handling the "ethyl" products and gasoline, owing to pulmonary and skin absorption.

The toxicological work of the Bureau of Mines deals with exhaust gases from engines using ethyl gasoline as commercially sold. The exposures were made to simulate the worst conditions as to time of exposure and concentration of gas in the air to which persons might be exposed without being poisoned by the carbon monoxide of the exhaust gases. The tests were continued over a period of eight months in order to bring out cumulative effects. Several species of animals (dogs, rabbits, monkeys, guinea pigs, and pigeons) were exposed for certain periods (up to six hours daily). Observations of growth, body weight, blood changes, symptoms of lead poisoning, pathological changes and lead storage in organs were also made. The amount of lead retained by men inhaling lead dust was also determined.

As far as retention of lead by human subjects was concerned, it was found that the inhalation of from 0.018 to 0.293 mgm. lead per cubic foot of inhaled air caused a retention of from 0.002 to 0.049 mgm. per cubic foot, or a range of from 8 to 27 per cent, average 15 per cent. It is stated that this behavior of the lead that remains in the air as suspended matter greatly reduces the dangers of lead poisoning. The investigators appear to regard the lead retention studied by their method as indicating pulmonary retention, but they also mention the possibility of retention in the nasal passages and throat and of swallowing or expectoration of the lead. The exact path of absorption is practically immaterial, because absorption of lead can occur from both the pulmonary and gastro-intestinal tracts. Probably the gastro-intestinal tract is of greater importance in man from the facts that contact with the hands after handling of lead is frequent and that certain investigators have demonstrated poisoning from the inhalation of a more volatile metal than lead, namely, mercury, without recognition of the metal in the lungs. Symptoms of chronic lead poisoning in man may develop only after continued exposure for months and years. Under modern conditions of intensive use of motor vehicles, for instance, in large and congested cities or on congested highways which teem with automobiles stirring the leaded dust and smoke for miles, day and night, the possibilities of both acute and chronic poisoning are apparent. In California, the passage of 60,000 automobiles in a day past a given point on a certain highway has been reported several times, and in this region the mitigating influences of rains and other weather conditions on the leaded dusts, etc., for the greater part of the year are absent. This puts the hazard of lead poisoning in a still different and menacing aspect.

As far as the exposure of animals to the different concentrations of lead that were used in the Bureau of Mines is concerned, poisoning, together with other changes in blood, body weight, etc., were negligible. Control or unexposed animals showed about the same changes, so that any changes could not be

attributed to the lead of the exhaust gases. With the exception of animals dying from causes ascertained to be other than lead, all remained normal as to activity, growth, appetite, and general signs of health. Any symptoms occurring were dismissed as not being in accordance with chronic lead poisoning. However, a period of eight months seems hardly long enough for ultimate determination of changes and symptoms of chronic poisoning, and the Bureau is continuing observations of certain animals for longer periods. It was found that lead storage in twenty-five analyses of carcasses, excepting digestive tract and skin, was of no significance from the standpoint of lead poisoning. The majority of the analyses showed 0.003 mgm. of lead in 100 gms. of body tissue, a quantity similar to that of unexposed or control animals. The investigators mention that considerably larger quantities (0.9, 2.08 mgm., etc.) than found in animals have been reported as occurring in proportionate weights of human tissue from individuals having no symptoms of plumbism and no recent exposure to lead. This suggests the possibility that ultimately lead may be regarded as a normal constituent of the tissues and excreta.

The results of the Bureau of Mines and other investigators indicate that lead is a constant constituent of unpoisoned and apparently normal animals, though it probably was not intended that way by nature. Such animals must have been, and perhaps most of us are, exposed to lead at some time. Even if man is not directly exposed to the metal, lead may conceivably occur in his tissues. An increase in the indirect occurrence perhaps may be looked forward to, for when the extensive and increasing use of motor vehicles, flying machines, etc., is contemplated, the spraying of our vast countryside with lead gives pause for thought. The leaded vegetation consumed by animals will produce stores of lead later to be consumed with meat, to say nothing of the direct consumption of certain leaded vegetables by man. In this connection, the reports of certain British veterinarians on the occurrence of lead poisoning in grazing cattle, in poultry, etc., and of the poisoning of land are of interest. This shows the problem of chronic lead poisoning in its larger proportions. The Bureau of Mines concludes that the only danger of lead poisoning from products of combustion from ethyl gasoline seem to be confined possibly to the mechanic who is continually cleaning carbon from motors, and although this is but a possibility, it merits precaution. In summing up the investigation it is stated that there has been no indication of plumbism in any of the animals used, though they were exposed for 188 days during a period of approximately eight months to exhaust gases from "ethyl gasoline" in concentrations with respect to lead content that are several times that allowable from the standpoint of carbon dioxide. Further work on lead poisoning in dogs and monkeys, and which it is hoped will cover the desired feature of greater chronicity, will be looked forward to.

It should be added that lead triethyl, which is closely related to lead tetraethyl, is poisonous to animals, but only after some time. That is, the lead is liberated gradually, and the occurrence of serious

symptoms is delayed. This was the compound originally used by Harnack in 1878 for producing experimental chronic lead poisoning. Further investigation along different lines may reveal, therefore, that lead tetraethyl, as a constituent of "ethyl gasoline" and similar mixtures, is a greater hazard than appears at present. When the difficulties of the diagnosing of early lead poisoning are borne in mind, the entire subject is certainly far from being closed. On the contrary, certain approaches are just being made, and, if confirmed and extended, may ultimately give a better understanding of the nature, prevention and treatment of chronic poisoning in man.

THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA. CALIFORNIA MEDICAL ASSOCIATION

The above old and new titles of our state association form a baffling and elusive puzzle to the general membership of the California Medical Association. It recalls our childhood struggle to decide if Ernest Seton-Thompson was Ernest Thompson-Seton, or some other Ernest.

By a differential diagnosis, the points of similarity and of dissimilarity may be pointed out and the blurred picture become clearly defined.

POINTS OF SIMILARITY

1. Both the California Medical Association and The Medical Society of the State of California have been titles used for our state association.

2. Both societies have the same dues and the same fiscal year.

3. Both societies use the same secretary and almost the same membership cards.

POINTS OF DISSIMILARITY

1. The California Medical Association is the present name of our state association. The Medical Society of the State of California is the former name of the state society, now used by a society formed of a group of members of the California Medical Association who desired optional medical defense furnished by the legal staff of the state association.

2. The dues of the California Medical Association are paid to county secretaries. They are NEVER PAID TO THE STATE SECRETARY. The dues for optional medical defense are paid direct to the secretary of The Medical Society of the State of California who, to add to the confusion, is one and the same as the state secretary.

3. The stationery, membership cards, assessment statements, etc., of the state association are printed on white paper. The stationery, membership cards, assessment statements, etc., of optional medical de-

fense furnished by The Medical Society of the State of California are printed on brown paper.

SUMMARY

Pay California Medical Association dues and also your county dues at one time to your county secretary; pay your optional medical defense dues to The Medical Society of the State of California, with offices at 1016 Balboa building, San Francisco.

THE ATLANTIC CITY SESSION OF THE A. M. A.

Reduced Railroad Fare to Atlantic City

The rate of one and one-half fare for the benefit of members and Fellows of the American Medical Association who will attend the annual session in Atlantic City, May 25-29, has been granted by the railroads. The member, when purchasing his ticket pays the full one-way fare to Atlantic City, at the same time securing his certificate from the railroad agent. This certificate will be approved at Atlantic City by the secretary of the association, must be validated by a representative of the railroads, and will then entitle the holder to a return ticket at one-half fare. The validation desk will be located near the Registration Bureau on the Steel Pier.—A. M. A. Journal, February 14, 1925.

CALIFORNIA PIONEERS IN PHYSIO- THERAPY DEVELOPMENT

Hahnemann Hospital of the University of California did pioneer work in establishing a large, well-equipped physiotherapy department, with doctors to prescribe and trained physiotherapists to apply these instructions in the treatment of disease on a large scale.

Stanford University Medical School did pioneer work in establishing the first scientific course for the training of physiotherapy technicians. The California Association of Physiotherapists again were so far-seeing in their method of organization that their constitution and by-laws have largely been adopted elsewhere and by their national association. Columbia University has recently added courses of instruction modeled upon those of Stanford, and hospital physiotherapy departments modeled upon the one at Hahnemann are now widely scattered.

We have only recently heard that Robert A. Kilduffe has resigned his position as Medical Director of the Los Angeles branch of the Pacific Wassermann Laboratories, and contemplates returning to the East. Though Dr. Kilduffe has been in this state but a comparatively short time, he has firmly established his reputation as a careful and reliable serologist, as well as a laboratory worker from whom valuable contributions could be expected in his chosen field. As a matter of fact, the employment of men of the type of Dr. Kilduffe can only redound to the benefit of institutions seeking the patronage of reputable physicians, who in turn fully appreciate the value and limitations of laboratory assistance in their work, and know full well that only too often many so-called technicians employed in commercial laboratories are incompetent, untrained youngsters, far better equipped to act as messengers or janitors than as serologists. We almost feel that the profession in Los Angeles must have neglected its opportunities in permitting Dr. Kilduffe to leave their midst. It might be interesting to hear from them as to his reasons for going. Possibly the Pacific Wassermann Laboratories might throw some light on the matter.

Is It Too Late to Begin?—"It is useless to look to the courts alone for any material help in dealing with cults, double standards of professional education requirements, or the perpetration of frauds by crooked doctors. *The first thing to do in every state is to procure an act of the legislature that will reflect wisdom and justice,*" is the opinion of H. E. Kelly of the Chicago bar.

Medicine in the Public Press

Besmirching the Memory of the Beloved Pasteur—The author of a so-called health column in a San Francisco newspaper, in speaking of the illustrious Pasteur, says that he was a "man of shallow, showy parts and superficial acquirements, pre-eminently a self-seeking advertiser and money-changer."

"Are the Colonel's Lady and—"—"Some time ago," says Warden Johnson of San Quentin Prison, "comparisons were made between mental ratings given to various prisoners by the prison employes and those secured by mental tests. It was found that they were almost identical. Depending on your personal viewpoint, you could say that the psychologists had done very well in this case, or that the prison guards were very efficient."

When Will California Learn This Lesson?—Dr. Howe, Director of Medical Inspection of Public Schools in the State Department of Education, New York, insists that it is not the policy of the Department of Education to have medical and preventive work performed in the schools. They strongly oppose it and advise against it. The function of the schools is education in health and health matters, and all vaccinations, immunizations, corrective work, etc., should be done outside the school by the family physician, or at a dispensary.—New York State Journal of Medicine.

Increased Social and Moral Responsibility Rather Than Technical Skill Needed—"The school ideal must be shifted. The school must train not for efficiency alone, but it must be the instrument of liberal culture," believes Edward W. Bok (Scribner's); "the means of awakening and ministering to all the higher instincts; the means of refining the soul and purging it of all that is base and ignoble; the means of stimulating to the higher forms of unselfish social service."

"We shall continue to teach the vocational subjects. We shall still need the technical and trade schools. But the ideal ends to be gained must be changed. The vocational courses should have some time for literature, history, sociology, art, and ethics. The lawyer, doctor, engineer, and tradesman all need these as much as they do the technical branches. The great problems of the world which demand immediate solution, if our civilization is to endure, are not primarily questions demanding technical skill, but are social and moral questions. There is skill enough, scientific knowledge enough, available if there were only courage enough, honesty enough and unselfishness enough in applying the knowledge. No one of them demands any great amount of shrewdness or technical skill. A STRICT APPLICATION OF THE TEN COMMANDMENTS WOULD SOLVE ALMOST EVERY REALLY GREAT QUESTION CONFRONTING THE WORLD."

Some newspapers are treating seriously the sayings of another "celebrated psychologist" who claims that:

"There are no mental or moral differences between children at birth."

and that

"Likes and dislikes, courage and timidity, a mild or a violent temper, are all absent from the child nature when it is born."

Osteopaths Now Recognized by the Industrial Accident Commission—Under the terms of a recent ruling by the Industrial Accident Commission of California, osteopaths now have precisely the same rights and privileges as do doctors of medicine.

William Lyman Phelps Points a Moral—The most amusing French comedy now running in Paris is "Knock" (pronounce the initial "K") or, "Le Triomphe de la Medecine," written by Jules Romains. This is a delightful satire on physicians, on patients, and on humanity. Young Doctor Knock is just the opposite of Monsieur Coue.

Coue endeavors to persuade sick people that they are well; Knock persuades well people that they are sick, a much easier task. He enters a village where illness is practically unknown, but he soon has all the inhabitants in a sanatorium, by the simple process of beginning with *free examinations*. He shows his visitor a chart: "This is the way your liver ought to look," whereupon he exhibits another and most horrible chart; "and this is the way your liver really does look." Diagnoses take place on the stage; and the various village types that enter the doctor's office are amazingly well done. Those who come to scoff depart in terror, with a long list of medicines, appointments, and bills in store for them.—Scribner's.

Doctor! How Could You!—The patients of "Doctor" — appeared to be getting quite a "kick" out of "sun baths" taken in the nude plus a few shocks of electricity, until Mr. Carter of the Board of Medical Examiners took a "look see" at the SANITARIUM (?).

The Osteopathic Bloc in Women's Clubs—Like all great organizations, women's clubs have to deal with organized groups—blocs—within their own organization. The newly formed Osteopathic Women's Association now beginning to function in California, said to be devised to "promote the welfare of women and children," gives promise of interesting developments.

Is This the Result of "Health Education"—People who now use tobacco have been widely, expensively, and intensively "educated" from earliest childhood about the alleged iniquitous influences of tobacco upon health.

Is it in consequence of this "education" or in spite of it that the consumption of tobacco has increased fourfold in the last two decades? We are now consuming, according to official government figures, 63,000,000,000 cigarettes annually, and the consumption is increasing in direct ratio to propaganda for suppression of the "vice" (?).

"Health education is great stuff."

California Board of Health Endorses Birth Control—Doctor Dickie, executive officer of the California Board of Health, is widely quoted in the public press as saying that:

"Fifty per cent of infant deaths may be attributed to congenital debility, malformation, premature birth, injury at birth, and other causes which are the consequence of unfit mating. Until such time as we may be able to control the growth of our population, infants will continue to die from congenital diseases. The health department can do little to reduce these cases. It is a problem in eugenics."

This statement will be discouraging to "prenatal hygienists," Sheppard-Towner "obstetricians," "health centers," "clinics," and other agencies who claim to be making such rapid progress in promoting "positive health."

A Severe Arraignment—American civilization is commonly regarded as essentially materialistic. It is said of us that we have contributed little or nothing to philosophy and to religion. Our symbolic products are Ford cars and standard plumbing fixtures. . . . And yet no people of modern times have struggled so poignantly to find spiritual expression. The evidence to this is ample, but unrecognized. That Americans are churchgoers and, in a large measure, members of the various orthodox Christian churches, everyone knows. But outside the orthodox ranks there are thousands, even millions groping toward God—struggling to relate themselves to the Infinite in some way that is satisfying to them. Out of these struggles have arisen the many new religions of America.—Jules Bois (The Forum).

Hospital Costs—This is the season for the publication of hospital reports for the year 1924. Most good hospitals report that the cost of service was a little higher for 1924 than it was for 1923. California State hospitals claim to be exceptions, and, according to press notices, they have decreased their costs.

There are two methods by which such reports can be made, and neither is anything to be proud of.

Are Chinese Herbalogists Above the Law?—Cal-

fornia law provides in effect that no one shall diagnose or treat, or hold himself out to diagnose or treat, infirmities of humankind without license from the appropriate state authorities. Every day, in the newspapers of California, Chinese herbalogists advertise and ask patients to come to them for "scientific diagnosis and for treatment by Chinese herbs, guaranteeing remarkable results, etc." There can be no question of doubt but that these herbalogists are violating state law in the claims they make in the advertisement published in the newspapers. There is no reasonable doubt but that they are also violating the law in practicing what they offer to practice in their advertisements.

We ask again, are they above the law and if so, why?

We are going pretty strong when we allow illegal practitioners of medicine to advertise publicly their illegal wares. We are informed by the Board of Medical Examiners, whose duty it is to prosecute these law violators, that punishments are too hard to secure. The reasons why this is so are whispered around and gossiped about wherever citizens gather. There is nothing mysterious about it, and CALIFORNIA AND WESTERN MEDICINE is very much disposed to put the whole truth regarding some of the instances into bold-faced type for the world to read. We hereby cordially invite the Board of Medical Examiners to supply us with the FACTS, and we will publish them regardless of consequences.

Unfortunate Publicity—The past few weeks have been merry ones in the exploitation of scientific work and scientific workers in the news columns. We feel sure that Doctor Herbert M. Evans and Doctor Martha R. Jones regret as much as do their friends the news slants given to their serious studies of serious subjects.

"He Who Breaks a Beehive Will Lick His Hand"—George W. Pratt (Survey) uses the statements and conclusions made in that glaringly misleading "Survey" of San Francisco's Health Condition made by Haven Emerson, in an attack upon the physicians and other health-serving people of the city. Pratt reiterates Emerson's untruthful statements that:

"Practically nothing is spent for health education (in San Francisco), hardly anything is done for mental hygiene; there are practically no visiting nurses for the bedside care of the sick. Hospital and dispensary services are reported as fairly adequate in quantity, but are submitted to much criticism as to quality. One wonders whether adequate educational forces exist to develop the higher standards in hospitals and dispensaries, and in social and health services, that are suggested at many points by this survey."

Members of our medical organizations; some of our good hospitals, and many of our physicians who are just as well prepared and just as well known in *scientific circles* as these self-appointed critics resent imputations like the above that are given wide publicity. If the Emersons and Pratts will actually show some peculiarly creditable results in health improvement in their home towns, we will be glad to adopt them and equally pleased to credit them with the original discovery. In the meantime, why not omit some of the blah-blah?

Hospitals Secure Advertising Through Society Columns of Newspapers—The cheap and unethical custom of certain small town hospitals to secure advertising for themselves and the doctors by featuring their patients and their illnesses in the local newspapers is too reprehensible to discuss in temperate language. Marked copies of newspapers carrying this disgusting form of advertising are numerous in the editor's mail. Some of these papers are accompanied by notes of protest apparently from the patients. There are effective methods of stopping these violations of good taste and ethics, and they ought to be utilized.

The present-day mocking appeal to an infant that he give expression to himself represents the abdication of education. This appeal might just as well be directed to a physical vacuum. To starve youth by depriving it of intellectual and moral nourishment, and to cripple and disable it by depriving it of the discipline of experience,

are among the newest and most popular forms of cruelty that have been devised to make education impossible. The results are apparent on every hand.—Nicholas Murray Butler, President Columbia University.

Disease Still Increasing—Some years ago, the American Association for Labor Legislation compiled the following startling estimations based upon the occupied males and females in the United States at that time:

Estimated number of cases of sickness among persons exposed to risks, thirteen and one-half millions.

Estimated social and economic cost of sickness per annum, a billion dollars.

Estimated number of days of sickness per annum, two hundred twenty-five millions.

"Full Time" School Physicians—The public school authorities in New York are employing "full time" doctors at \$1000 a year to look after the health of school children. They also have "full time" "nurses, health teachers and other experts," but they pay these more than they do their doctors.

They call attention in print to this "progress" as something to be proud of.

Physicians Attacked for Not Giving—A Community Chest speaker at a recent Community Chest luncheon in San Francisco drastically criticized the doctors, among others of the "semi-rich" or "great middle class," for not "coming across" with more money for the "chest." Newspapers quote the speaker as saying:

"It is the big class of professional and semi-rich. It is the lawyers, doctors, dentists and other professional men who send their office assistants out to talk to those who are devoting their time to collect the funds needed to adequately care for San Francisco's needy.

"We should shame these people into giving. If they knew that a list of those subscribing was to be published, they would feel obligated to come across. I become blind with rage when I know the needless obstacles our workers are meeting."

The reaction against this tirade was prompt, widely spread; and the end is not yet. As has been repeatedly published, the doctors of San Francisco and elsewhere as well, give to charity in *service*, figured as nominal value, every year more than the entire collections of the Community Chest. Doctors don't want any special commendation for such helpfulness. It is part of every day's work with every one of them; but they do resent deeply and widely ill-advised criticism of the kind mentioned.

One of the most prominent and most beloved physicians in the city informs us that on the very day that doctors were being publicly attacked at this chest luncheon, he saw nine poor patients in his office, and performed major operations upon two persons, none of whom would ever receive a bill for either medical or hospital services. Incidentally, the hospital thus giving its charity is one dismissed by that notorious Haven Emerson "survey" for the Community Chest as "commercial" and, therefore, by implication beyond the pale. According to the statements of certified public accountants, that hospital rendered free service to the poor last year that cost them over \$75,000 to give. Other similar stories of individual and group interests in the welfare of dependent citizens could be told and verified—but what's the use?

The constantly increasing difficulties of raising sufficient funds to carry forward the program of the Community Chest is, of course, apparent to all. The chief reasons ought to be equally apparent to any competent observer. The dangerous tendencies and the reasons therefor should be fairly evaluated, and the policies and methods of the fundamentally fine principle of uniformity in collecting and allocating charitable funds and services be revised accordingly.

Free Birth Control Health Centers Halted—Just when the free "clinics" and "health centers" devoted to "birth control" get well started, the courts of Illinois take all the joy out of "careless love" by declaring these "free health centers" as illegal because they are practicing medicine without a license.

California Medical Association

GRANVILLE MacGOWAN, M. D., Los Angeles...President
EDWARD N. EWER, M. D., Oakland.....President-elect
EMMA W. POPE, M. D., San Francisco.....
.....Secretary and Associate Editor for California

THE ANNUAL SESSION, C. M. A., YOSEMITE,
MAY 18-21, 1925

To the average person unfamiliar with the mountains, the term "cabin resort" conjures up some dreadful vision of sleeping on the ground and eating from a tin plate. Let it be said here, for the benefit of those who will attend the 1925 convention of the Medical Society of the State of California in Yosemite National Park, May 18-21, that such a trip involves no hardship or sacrifice of comfort.

"Why, it isn't like the mountains at all," exclaimed one woman from the East, a guest at Yosemite Lodge, when she learned that she could have her breakfast, piping-hot, served at her bedside any morning that she desired to give the order.

Such a comment was not intended to mean that the noble cliffs and waterfalls of Yosemite Valley had been ruined by the erection of buildings out of keeping with the natural surroundings; rather it was a spontaneous compliment to service rendered at the Lodge, fifteen miles from a railroad, service that measured up to standards of city hotels and far exceeded what the visitor had found at mountain resorts in other sections.

Yosemite Lodge is a little city in itself. "A charming colony of redwood cabins under the pines at the foot of Yosemite Falls, the cabins being grouped around a community center of office, dining room, lounge, writing-room, dance pavilion, theater, swimming pool, children's playground, and nightly camp-fire," is the description usually given of it.

The Lodge has its own postoffice, the name of which is Yosemite Lodge, California, and mail so addressed is delivered direct from trains without the delay of going through the main office in the village, the name of which is Yosemite National Park, California. The Lodge otherwise has its own telegraph station, Yosemite Lodge, California, and long distance telephone facilities. Baggage can be checked straight through to Yosemite Lodge.

In the American Plan dining-room of the Lodge, there is individual service for each guest. The dining-room linen is snowy white, and waitresses and bus boys are uniformed in white.

The other public rooms and broad verandas of the Lodge main group need no special mention, but a word should be said here about the services in the swimming pool group, just across the plaza. The pool is 120 feet long, filled with crystal mountain water which is heated to a comfortable temperature by steam. Suits can be rented. After a plunge, there is a barber ready to serve the men, a beauty parlor with all modern equipment for hairdressing, facial treatment, and manicuring for the women. The laundry, in the same group, offers high-class service, including the cleaning and pressing of clothing.

Every evening there is an entertainment of merit

at the Lodge free to all guests. Every evening except Sunday there is dancing to the music of an excellent orchestra.

A word also should be said about the "cabins" which make up the Lodge's living quarters. Three types of cabins are provided.

The first type is built of redwood in rustic style that harmonizes with the tall pines and spruces around. A generous porch gives entrance to a bedroom with twin beds and other furniture of special design and finish. Dressing room, closet or wardrobe provides ample space for hanging up clothes. The bathroom includes tub, washbasin, and sanitary flush toilet of spotless porcelain; in a few of the cabins there are shower baths. Many of these cabins also have screened and curtained sleeping-porches on the rear. Electric stoves furnish heat at a turn of the button. American Plan rate, \$8.50 per day per person.

Redwood cabins without bath make up the second group. Like the cabins with bath, they are furnished with twin beds. Bowls and pitchers are provided, and small stoves burning fragrant cedar or pine wood are used for heating. American Plan rate, \$6 per day per person.

Canvas cabins form the third group—and do not confuse the Lodge's canvas cabins with tents. Canvas cabins here are all that the name implies—houses with canvas for walls. They are floored, have electric lights, a screened door, and six screened windows with awnings and curtains. Furnishings are similar to those in the redwood cabins without baths. European Plan rate. (lodging only) \$1.50 and \$2 per day per person. American Plan rate (with meals in Lodge dining-room), \$6 per day per person.

Maid service in all cabins assures plenty of towels and, in the cabins without bath, fresh water also. Hot water for the morning toilet may be had without extra charge by those living in cabins without baths, by leaving number of cabin and hour desired at the office of the Lodge.

YOSEMITE LODGE RATES

Yosemite Lodge is a colony of redwood cabins and canvas cabins in the pine woods, with central group buildings, including dining-room, office, lounge, writing-room, swimming pool, tennis courts, laundry, children's playgrounds, etc.

Redwood cabins with bath have front porch, living-room with twin beds, and many have in addition screened sleeping-porch with twin beds. Redwood cabins without private bath have living and sleeping compartments and twin beds. Canvas cabins have twin beds, are electric lighted, and have windows.

Redwood cabin, with bath, three or more persons in a single cabin, or half of a double cabin, per person per day, American Plan.....\$8.00

Redwood cabin, with bath, two persons in a single cabin, or half of a double cabin, per person per day, American Plan.....\$8.50

Redwood or canvas cabin, without bath, two persons in cabin, per person per day, American Plan.....\$6.00

Canvas cabin, without bath, two or more persons in cabin, LODGING ONLY, European Plan, per person per day.....\$2.00

European Plan guests will be served meals in cafeteria. Tub and shower baths in detached rooms.....50c

Send all reservations direct to L. H. Marks, assistant to general manager, Yosemite Lodge, Yosemite National Park, California.

TRAIN SERVICE AND FARES TO YOSEMITE LODGE

From San Francisco, Oakland, Berkeley, and Alameda to Yosemite Valley and Return

Tickets good leaving starting place on a Friday, Saturday, or Sunday only, \$20.25. Return limit, 16 days.

Tickets good leaving any day, \$21.75. Return limit, 90 days.

From Los Angeles to Yosemite Valley and Return

Tickets good leaving starting place on a Friday, Saturday, or Sunday only, \$29.75. Return limit, 16 days.

Tickets good leaving any day, \$33. Return limit, 90 days.

From San Francisco, the train service will be as follows:

Southern Pacific, No. 84

Lv. San Francisco, 8:40 a. m. Ar. Merced, 1:15 p. m.

Santa Fe, No. 22

Lv. San Francisco, 9 a. m. Ar. Merced, 1:25 p. m.

Southern Pacific, No. 50

Lv. San Francisco, 3:40 p. m. Ar. Merced, 8:55 p. m.

Santa Fe, No. 42

Lv. San Francisco, 5:15 p. m. Ar. Merced, 9:48 p. m.

Santa Fe, No. 2

Lv. San Francisco, 11 p. m. Ar. Merced, 3:40 a. m.

Southern Pacific, No. 86

Lv. San Francisco, 11:40 p. m. Ar. Merced, 5:35 a. m.

Southern Pacific, No. 84

Lv. Merced, 1:40 p. m. Ar. Yosemite, 7:15 p. m.

Santa Fe, No. 22

Lv. Merced, 1:50 p. m. Ar. Yosemite, 7:15 p. m.

Southern Pacific, No. 50

Lv. Merced, 8 a. m. Ar. Yosemite, 1:15 p. m.

Notes—

Southern Pacific train No. 84 carries diner.

Santa Fe train No. 22 carries diner and parlor car.

Southern Pacific train No. 50 carries diner.

Santa Fe train No. 42 carries diner and parlor car.

Southern Pacific train No. 86 and Santa Fe train No. 2 carry standard Pullman sleepers to Merced. Sleepers are detached at Merced. Occupants will not be obliged to vacate until just time enough to get their breakfast and depart from Merced on Yosemite Valley railroad at 8 a. m.

From Los Angeles, the train service will be as follows:

Southern Pacific Train No. 59

Lv. Los Angeles, 6:15 p. m. Ar. Merced, 5:35 a. m.

Lv. Merced, 8 a. m. Ar. Yosemite, 1:15 p. m.

Note—

Southern Pacific train No. 59 carries standard sleeper to Merced. Sleeper is detached at Merced. Occupants will not be obliged to vacate until just time enough to get their breakfast and depart from Merced on Yosemite Valley railroad train at 8 a. m.

Pullman Rates—

San Francisco to Merced:

Parlor-car seat, \$1.05; lower berth, \$3; upper berth, \$2.40; drawing-room, \$10.50.

Los Angeles to Merced:

Lower berth, \$3.75; upper berth, \$3; drawing-room, \$13.50.

ATLANTIC CITY

Train information for members who plan to attend the A. M. A. meeting at Atlantic City from May 25-29.

Southern Pacific "Overland Limited"

Lv. San Francisco, 11 a. m., May 22. Ar. Chicago, 8:55 a. m., May 25.

Pennsylvania "Broadway Limited"

Lv. Chicago, 12:40 p. m., May 25. Ar. No. Philadelphia, 7:54 a. m., May 26.

Pennsylvania

Lv. No. Philadelphia, 9:56 a. m., May 26. Ar. Atlantic City, 11:05 a. m., May 26.

Lower berth, San Francisco to Chicago.....\$23.63
Upper berth, San Francisco to Chicago..... 18.90
Compartment, San Francisco to Chicago..... 66.75

Drawing-room, San Francisco to Chicago..... 84.00
Lower berth, Chicago to Philadelphia..... 8.25
Upper berth, Chicago to Philadelphia..... 6.60
Compartment, Chicago to Philadelphia..... 23.25
Drawing-room, Chicago to Philadelphia..... 30.00

Extra fare, Broadway Limited, \$8.40.

One-way fare to New York via Atlantic City is \$108.90. Summer rates commence May 22. Round trip to New York via Atlantic City is \$151.15.

Delegates, alternates, Fellows, and members of A. M. A. are entitled to one and a half regular rate.

Should a party plan to leave on a given date, reservation for a special car can be made.

The above schedule gives the shortest time between San Francisco and Atlantic City. Many other trains are available.

ALAMEDA COUNTY

Alameda County Medical Association (reported by Pauline S. Nusbaumer, secretary)—The regular meeting of the Alameda County Medical Association was held January 19, H. B. Mehrmann presiding. After the reading of the minutes the program arranged by G. G. Reinle, consisting of a case report and a symposium on diseases of the urinary tract, was presented.

In his case report, W. B. Palamontain gave a brief review of bilharzia, and described the symptoms of a man extending over a period of twelve years before a diagnosis of bilharziosis was made. The case cleared up completely following some twelve injections of tartar emetic.

In the first paper of the symposium, "Kidney Function and its Relation to Nephritis," S. V. Irwin gave a brief outline of our present views on the anatomy and physiology of the kidney, after which some of the various theories concerning the process of urine production were discussed. The bearing of some of these facts upon kidney function and their relation to kidney function tests was then taken up with a review of the newer work of Richards on glomerular secretion, with a discussion of the practical application of this newer work.

Gertrude Moore, in her paper, "The Pathologic Kidney and Its Function," briefly reviewed the pathology of the kidney and discussed kidney function tests, the conclusion being reached that no single test could be relied upon, it being necessary to study both the retention products and the excreting power of the damaged kidney before surgical procedure.

In his paper, "Management of Prostatic Obstruction," G. G. Reinle said that the mortality rate for the operation of prostatectomy is: For the occasional surgeon, 25 per cent; for surgeons of all classes combined, 15 per cent; for surgeons using all known precautions, 3 per cent minus. He stated that the 15 per cent would be materially reduced by adequate preparation and post-operative care. The speaker thought it was merely a matter of individual preference as to whether an operator employed the supra-pubic or the perineal method of enucleation, though giving personal preference to the supra-pubic route.

It was pointed out that all prostatic obstructions do not require enucleation of the gland, and the other proper surgical methods of relief were discussed.

A full discussion of these papers was participated in by Thomas Addis (by invitation) of the Department of Medicine of Stanford University, W. S. Kuder, Mark L. Emerson, and others.

After the transaction of business the meeting adjourned to the lower hall, where refreshments were served and an hour of good fellowship enjoyed.

Fabiola Hospital Association—At the annual meeting of Fabiola Hospital Association the officers and directors re-elected were: Mrs. J. H. P. Dunn, president; Mrs. Wallace Everson, first vice-president; Mrs. J. H. Knowles, second vice-president and financial secretary; Mrs. Allen D. Wilson, third vice-president; Mrs. D. E. Easterbrook, recording secretary; Mrs. Q. A. Chase, treasurer; Mrs. James G. Allen, assistant treasurer; Mrs. John Shuey, corresponding secretary. Directors: Mrs. H. C. Taft, Mrs. E. A. Whitaker, and Mrs. Violet Whitney.

A gift of \$5000 was presented to the hospital by Mrs.

Carlotta Carson Tyson in memory of her parents, William and Sarah Carson. Dr. Daniel Crosby obtained a free laboratory fund of \$500 for the hospital, while Dr. W. L. Bell donated one of his fracture tables to the institution.

During the past year 694 children were treated with 730 days' free care, and 513 patients received medical care free of charge, which cost the hospital \$12,107.43. The yearly report of the treasurer of the hospital showed disbursements to the amount of \$428,712.94.

One of the official reports read, in part, follows:

"Many young women from all parts of the state are applying for admission to our school for nurses, but we are unable to accept all of them as our nurses' home is filled to capacity.

"Children to be restored to health and happiness always make the greatest appeal, and every effort is being made toward that end.

"The new maternity unit has been busy beyond all expectations. A total of 1101 babies were welcomed last year, and included in that number were twelve sets of twins.

"Another year has passed into the history of this institution—the forty-eighth, a year that may be considered the banner year of its existence, in point of service and development. May we be given the power to press on to still greater achievement for our blessed Fabiola."

Dr. L. H. Buteau Heads Society of Surgeons—Dr. S. H. Buteau is president of the Surgeons' Society of Oakland, which was organized recently. C. A. Dukes is vice-president and E. Spence DePuy is secretary-treasurer.

The purpose of the society, as described by O. D. Hamlin, chief of staff of Providence Hospital, is to discuss for mutual benefit the latest advances in surgery technique through the reading and discussion of papers on the subject, and the exchange of papers with similar societies in Eastern cities.

Eighteen local surgeons are enrolled in the society. A committee is now at work preparing a constitution and by-laws.

CONTRA COSTA COUNTY

Contra Costa County Medical Society (reported by L. St. John Hely, secretary)—The regular monthly meeting of the Contra Costa County Medical Society was held at the offices of F. L. Horne at Crockett on the night of January 31.

An illustrated lantern slide lecture was given by Nathan G. Hale of Sacramento on the pathology in general of the kidneys and ureters. Special attention was given to obstruction and blocking of the ureters. Great care and work was shown in the preparation and subject matter of the slides.

The following members and friends were present at the meeting, and gathered at the hotel for refreshment afterward: John Beard, Martinez; Denninger-Keser, Richmond; J. Emmett Clark, Walnut Creek; F. L. Horne, Crockett; Nathan G. Hale, Sacramento; William A. Rowell, Crockett; Rosa A. Powell, Richmond; Elizabeth Redmond, R. N.; L. St. John Hely, Richmond.

FRESNO COUNTY

Fresno County Medical Society (reported by T. Floyd Bell, secretary)—Two special meetings of the Fresno County Medical Society were held January 17; a noon luncheon at the Hotel Fresno; and a meeting in the evening at the General Hospital of Fresno.

Those present were: Aller, Anderson, Bell, Binkley, Couey, Cross, Craycroft, Diederich, Ellsworth, Goldberg, Jones, Jorgensen, Lamkin, S. M. Long, Manson, Mathewson, Miller, Montgomery, Mitchell, Mordoff, Morgan, Millholland, McPheeters, Pettis, Pomeroy, Pisor, Schottstaedt, Sheldon, Staniford, Stein, Scarboro, Tillman, Tobin, Trowbridge, Tupper, G. W. Walker, and Willson. Visitors: Drs. George Piness, E. R. Lewis, Hyman, Miller, Dau, and Mr. Alles.

At the noon luncheon George Piness of Los Angeles presented a very interesting and instructive discussion on "Allergy." He spoke of allergy in general, and also in relation to such specific conditions as eczema, migraine,

angioneurotic edema, urticaria, abdominal allergy, and so-called "arthritis" due to allergy.

Three papers were read on hay-fever and asthma at the evening meeting.

Dr. Hyman Miller of Los Angeles discussed protein sensitization and anaphylaxis. He described and illustrated the skin tests as he uses them. He emphasized the absolute specificity of protein reactions and the necessity of testing with the exact type of protein to which the patient is exposed. He insists that there is no doubtful reaction in the skin test. Any reaction showing pseudopodia like the extensions from the central wheel are to be regarded as positive. All others must be considered negative. Miller discussed the lung findings in his cases of fatal anaphylaxis and in severe asthma.

Mr. Gordon Alles read a paper on the chemical aspects of anaphylaxis and allergy.

George Piness gave the principal address of the evening on clinical aspects of allergy. He described the method of complete examination of patients sometimes extending over a period of years, the histories taken, the laboratory tests, the studies made of the patient's surroundings and habits. A number of very interesting cases were cited in which a distinctly local protein was responsible for the trouble. Methods of treatment, both palliative and specific, were given.

The regular meeting of the Fresno County Medical Society was held February 3 at the nurses' home of the General Hospital.

There were thirty-four members and eighteen visitors present. Members: Aller, Anderson, Bell, Barr, Couey, H. O. Collins, Deiderich, Dearborn, Dahlgren, Ellsworth, Goldberg, James Jorgensen, Kjaerbye, Larson, Manson, Maupin, Miller, Morgan, Nedry, Nider, Peterson, Pettis, Ransom, C. A. Robinson, Schottstaedt, Sciaroni, Stein, Scarboro, Tillman, Tupper, J. R. Walker, Webster, Weddle, and Wiese.

Drs. H. Robertson and N. J. Dau were unanimously elected regular members.

The board of censors and the state secretary having reported favorably on the application of Dr. H. O. Collins for associate membership, he was unanimously elected.

President Anderson announced the standing committees for this year, as follows:

Program Committee—Madden, Barrett, and Manson.

Board of Censors—Morgan, Pomeroy, and Wiese.

Committee on Ethics—Tupper, James, and J. R. Walker.

A communication from the Gorgas Memorial Institute of Tropical and Preventive Medicine was read and ordered laid on table.

A letter from Dr. O. W. Steinwand was read, thanking the society for conferring upon him honorary membership.

A communication was read from Dr. Ellen Stadtmuller, director Bureau of Child Hygiene California State Board of Health, in regard to examination of children entering school for the first time. Dr. Morgan moved, Dr. Madden seconded, that the board of governors work out a plan for caring for this matter. Carried.

J. R. Walker spoke briefly against the practice of consulting and working with any members of cults in treating patients.

Emmet Rixford, Professor of Surgery Stanford Medical School, gave a very interesting and instructive lecture on "The Mechanics and Production of Fractures, With Special Reference to Spiral Fractures of Long Bones." Dr. Rixford is especially capable of dealing authoritatively on this subject, as he received an academic education in mechanical engineering. He dwelt at some length on the mechanical results of traction and twisting of various materials. He showed how these same principles applied to fractures, especially the spiral fractures of long bones. He showed his personal treatment of these spiral fractures, how easily the fragments could be held in position by open reduction. While the talk was highly technical, yet it was very logical and in the end simple.

A buffet luncheon was served after the meeting.

The annual meeting of the staff of the General Hospital of Fresno County was held January 13 at the Sequoia Club at dinner. There was a good attendance. Dr. Frank Tillman acted as toastmaster of the evening.

A communication from Director H. O. Collins was read.

Frank Curtin, a local attorney, gave a very humorous talk entitled, "Glass Eyes I Have Known."

The following officers were elected for the ensuing year: President, Thomas F. Madden; vice-president, Guy Manson; secretary-treasurer, Charles A. James.

Annual Report (presented by T. Floyd Bell, secretary, December 31, 1924)—The regular and two special meetings of the Fresno County Society were held during the year 1924, with a total attendance of 413, or an average of 34.4 members to each meeting. The two special meetings were noon luncheons, started in November, which have proven popular with the men. Scientific programs were given at all the meetings except one—a get-together meeting on December 2.

One year ago the secretary reported 118 active and six honorary members. During the year seven members have been dropped for non-payment of dues: Drs. Brown, Hoare, Minas, Stammers, Steinwand, Flora W. Smith, T. D. Smith. Three new members paid for the year 1924: Drs. S. M. Long, H. M. McNeil, and G. C. Nedry. The total active members for 1924 were 114, and six honorary members. R. M. Jones was transferred to the Kern County Medical Society. A. B. McConnell was lost through death last August.

The following physicians were recently elected: G. K. Nider, R. W. Dahlgren, and C. B. Cowan. The application of O. P. Pisor having been passed on favorably by the state secretary, will be voted on January 6, 1925.

During the past year we have had many interesting programs presented to us by able men, most of them from medical centers. Those who attended the meetings know the merits of these scientific papers.

Early in the year a movement was started to re-establish our medical library, which is housed and taken care of by the Fresno County Library. Due to the generosity of several members, subscriptions to the various periodicals were renewed and some of the old files completed. It is hoped that a small amount of money will be expended each year to keep the files intact, as they will be invaluable as time goes on.

Noon luncheons held once a month bring about a better understanding among the members of our profession, and create firmer friendships and more constant and effective general co-operation between the men. Out-of-town men are urged to attend whenever possible.

LOS ANGELES COUNTY

Hollywood Hospital Accredited by American Medical Association—The Hollywood Hospital has been placed on the list of hospitals accredited by the Council on Medical Education and Hospitals of the A. M. A. We welcome this new addition to the hospitals that are devoted exclusively to the promotion of scientific medicine.

PLACER COUNTY

Placer County Medical Society (reported by Robert A. Peers, secretary)—The Placer County Medical Society held its February meeting at Auburn, Saturday evening, February 14. The following members and visitors were present: Members—Doctors H. N. Miner, L. B. Barnes, R. H. Eveleth, H. M. Kanner, C. E. Lewis, J. G. Mackay, R. F. Rooney, R. O. Schofield, G. H. Fay, R. A. Peers. Visitors—P. D. Barnes, R. N. Bramhall.

At the close of the regular business, R. N. Bramhall of Sacramento delivered an address on diabetes. Dr. Bramhall took up the history of the work done on the pancreas from the first pathological reports published in the late eighteenth century down to the recent work by Banting and Best. He described very fully and very clearly the physiology of digestion of carbohydrates, proteins, and fats, and explained the break in the normal physiology of digestion which resulted in a train of symptoms known as diabetes. He also outlined the chemistry of the blood and concluded with a resume of the present methods of treatment, both dietetic and by insulin, paying particular attention to the treatment of diabetic coma. After the address there was an informal discussion in which all the members took part.

SACRAMENTO COUNTY

Sacramento Society for Medical Improvement (reported by Bert S. Thomas, secretary)—The January meet-

ing of the Sacramento Society for Medical Improvement was held at the new Sutter Hospital. Thirty-five members attended. There were four visitors.

Presentation of Cases—Dr. Schoff presented two patients. The first was that of an epithelioma of the nose. The patient was presented to show the results of radium treatment. This patient had had three treatments in the last year. It demonstrated that the Prickle cell type keeps growing despite the treatment, the radium merely quieting it for a short time. The second patient showed a most diffuse psoriasis. He was shown to call attention to the marked likeness of the lesion to a papulo-squamous syphilid.

Dr. Rulison presented a five-pound degenerated myoma that had been removed at a transperitoneal Caesarean section for a full-term baby. The case had been seen at the third month and had raised a question as to the possibility of a bicornuate uterus.

Dr. Hale reviewed four cases of traumatic hematuria. One, of an upper pole rupture causing a capsular hematoma. This case required nephrectomy. The second, a hemorrhage from the kidney pelvis, was controlled by the introduction of a 3 per cent AgNO₃. The third bled from the veins immediately adjacent to the kidney pelvis. Here a hematoma was removed and an iodoform pack controlled the hemorrhage. The last was of a buckshot lesion of both kidney and ureter. This was controlled by transfusion plus the introduction of a ureteral catheter, which was left in place for three days. Dr. Snyder remarked about the interesting fact of being able to obtain the rare Type 1 donor for this last case, who was also a Type 1.

Dr. J. Roy Jones presented a most interesting paper. His subject was "Nasal Headaches." He stressed the supreme importance of the nasal sinuses in connection with his subject. Despite the goodly supply of blood vessels and lymphatics, the nerves are the 100 per cent offenders in the distribution of the distress. Special attention was directed to the great ramification of the fifth nerve in this regard. As direct causes, toxemia and pressure were shown to be of first consideration. The latter manifests itself by first, pressure on points impinging on the sinuses; second, by malposition of structure; third, pressure by congestion within the sinuses; fourth, pressure due to pus; and lastly, by negative pressure, i. e.: that due to a blocked outlet. This usually occurs in the frontals and ethmoids. All the above causes may be precipitated by acute coryza. Here all the elements of the blood are found in the cavities by transudation. These, in turn, become infected. Extra body strain, abuse of alcohol, indigestion, and constipation, all exaggerate the picture. Though most writers suggest that the headache itself is not caused by the peripheral irritation, Jones takes issue with this statement.

Under treatment of the conditions causing "nasal headaches," Jones discussed the palliative treatment by inhalations. This may be used diagnostically. If relief is thus afforded, it most surely points to accessory sinuses or their adjacent orifices as involved. This is particularly effective when thickened secretions enter the picture.

In the discussion, George Briggs differentiated between the suppurative and non-suppurative type. He pointed to the narrowed nose, giving turbinate pressure and blocked openings, as an important factor. McKee suggested that practically all sinus infections are associated with some deformity, and called attention to the fact that immediate treatment of numerous childhood injuries would obviate a good many later difficulties. He also complimented the orthodontists on their good work in preventing these later conditions. Turner considered irritation of a recently discovered portion of Nerve 1, called the terminal nerve, to be an important factor; also, ostealgias about the nerve openings.

Dr. Miller discussed Ewings' sign. Harris inquired of the value of chlorine gas in treatment. Jones stated that he believes chlorine gas treatment of these conditions will not be successful.

The board of directors reported the election of F. N. Scatena as president and W. W. Cress as vice-president. A program committee, consisting of Drysdale and Dunlap, was appointed.

Communications were read from Dr. Dickie, inquiring

as to the local status of endemic goiter, and from Hartley Peart, regarding group insurance.

Resolutions to perpetuate the memory of Doctor James were prepared by Drs. Simmons and Hall, and ordered spread upon the minutes.

Dr. Parkinson called attention to the fact that the magazine BETTER HEALTH was being placed on a self-supporting basis.

Immediately after adjournment, a real surprise was in store. Dr. June Harris presented a most beautiful piece of statuary to Dr. W. H. Beattie. The piece is entitled "Maternity" and depicts a mother with two babies. The mother is fondling one, and there is an appeal from the other, now much older, to be fondled. This beautiful work of art was exhibited by the kindness of Mrs. Spreckels at the Panama-Pacific International Exposition, and was to be placed in the De Young collection until Dr. Harris was fortunate enough to obtain it for presentation to Dr. Beattie. The piece will be given a prominent place in the Sutter Hospital.

Local Notes—Dr. Thom, recently on the x-ray staff of the University of California Hospital, is established here with Dr. Zimmerman.

Dr. Edward S. Babcock's many friends of the Bay region will be pleased to hear of the arrival of "Miss Phillis" on January 19.

The beautiful new Sisters' Hospital of 150 beds intends opening its doors on January 25.

The staff of Sutter Hospital has named E. T. Rulison chief, and James R. Snyder, assistant.

E. C. Turner has returned from European clinics and is established in his new offices for the practice of ear, nose, and throat work.

R. G. Scribner has affiliated with the local society. He comes from Hammononton.

SAN DIEGO COUNTY

San Diego County Society (reported by Robert Pollock, editor)—The recent meeting of the Southwest section of the American College of Surgeons was a most noteworthy affair. That talks on medicine can so attract the public as to draw 4000 people and turn away hundreds who could not be accommodated, is sufficiently unusual to be noteworthy in itself. The speakers at these public meetings are doing a valuable work; valuable not alone to the public, which needs to be better informed upon the ideals and human issues and contacts of scientific medicine, but valuable also to the members of the profession who are induced to think in terms of human interest and social tendencies, as well as in the daily grind of scientific thought. California and Southwest medicine owes a debt of gratitude to Dr. Franklin H. Martin and his aides, Drs. Craig and MacEachern, as well as to Dr. George W. Crile and Father Moulinier. The scientific sessions to which the medical profession as a whole were welcomed were distinctly stimulating, and brought together a distinguished gathering of the leaders in surgery in the Southwest, San Francisco, Los Angeles, and other California cities contributing liberally their quota. Among other things brought out was the fact that San Diego can boast fifteen Fellows of the college. San Diego's newer hospitals, all of which conducted clinics during the convention, were greatly admired by visiting surgeons.

Through the generosity of John D. Spreckels, one of San Diego's foremost citizens, Mercy Hospital will be enabled to add an extra wing, leading from the south of the main building, to balance the recently completed north wing. This wing, which is a memorial to the late Mrs. Spreckels, will add much to the beauty and symmetry of the whole.

The officers and committee members of the San Diego County Medical Society for 1925 are as follows: President, George B. Worthington; vice-president, T. F. Wier; secretary, C. O. Tanner; treasurer, W. O. Weiskotten; editor, Robert Pollock; associate editor, W. H. Geistweidt, Jr.; librarian, Mrs. Mildred S. Farrow.

Delegates to State Society—Thomas O. Burger, two years (1924-5); Robert Pollock, two years (1924-5); Martha Welpton, 1925.

Alternates to State Society—M. C. Harding, two years (1924-5); L. H. Redelings, two years (1924-5); Lillian Mahan, 1925.

The County Medical Society has enjoyed some excellent programs at recent meetings, some of which are herewith mentioned: An illustrated lecture on "Non-Surgical Types of Backache," by P. B. Magnuson, M.D., of Chicago; A symposium on the treatment of tuberculosis with demonstration of artificial pneumothorax, and other features, furnished by the medical staff of Camp Kearny were very favorably received, upward of 100 members of the county society motoring out to the camp on the occasion of this annual treat.

It is of passing interest that the San Diego County Dental Society on January 15 centered its discussion around a paper on "Metabolism in Its Bearing Upon Dentistry," by Dr. Harvey Jackson, who is a member of both the medical and dental societies.

SAN FRANCISCO COUNTY

Meeting of the Eye, Ear, Nose, and Throat Section of the San Francisco County Medical Society, January 27, 1925—At the meeting of the Eye, Ear, Nose, and Throat section of the San Francisco County Medical Society on January 27, Dr. Pischel reported further progress in a most unusual case, the resume of which is as follows: A fine piece of copper from a dynamite-cap explosion lodged inside the eyeball on the ciliary body. The accident occurred twelve years ago. The eye at present shows copper deposits in the lens and glaucoma.

The foreign body was localized according to Sweet's improved eye localizer in the ciliary body 8 mm. below the center of the cornea, while localization with Dr. Pischel's markers (California State Journal Medicine, Vol. 18, October, 1920, p. 408) put it just inside of the sclera on the ciliary body.

December 16, 1924, a vertical incision through the sclera upon the foreign body was made; no foreign body was seen or felt. An extensive cyclodialysis was then added.

As the tension remained high, in spite of adrenalin injections, iridectomy upwards was performed December 19, 1924. A few days afterwards the patient went home. He reported January 6, eighteen days after the iridectomy. Tension was 30; eye pale, with the exception of the point of the incision, for the iridectomy under the upper lid, and there under the conjunctiva, was seen, with Zeiss Loup, a fine sharp-edged foreign body showing reddish reflex under the corneal microscope. The roentgen picture showed only this foreign body; none in the former location below the limbus. After slitting the conjunctiva, the foreign body was removed and proved to be a very fine piece of metal 1 mm. long.

How did the foreign body get there? Dr. Pischel's explanation is this: At the cyclodialysis the foreign body was pushed into the anterior chamber, and at the iridectomy it floated under the conjunctiva and became lodged there.

Franklin Hospital Staff Meeting (reported by Ewald H. Angerman, secretary)—The monthly staff meeting of the Franklin Hospital was held in the hospital on Friday, January 30, W. H. Heinzman presiding. Officers elected to serve for the ensuing term are: Chairman, Frank R. Dray; vice-chairman, Otto Westerfeld; secretary, Ewald H. Angerman.

The paper of the evening was ably presented by Irving S. Ingber, who chose for a subject, "Duodenal Diverticulitis," illustrated by appropriate lantern slides; also a presentation of case reports. The subject was discussed by Dray, Werner, and Yoell.

Southern Pacific General Hospital Clinical Meeting (reported by W. T. Cummins, secretary)—The monthly clinical meeting of the Southern Pacific General Hospital, San Francisco, was held in Huntington Hall, on Wednesday, February 4.

"Fulguration in Questionable Tumors of the Bladder," George L. Eaton. He spoke of the importance of this type of therapy and the careful following up of the patient, with subsequent diathermy every two or three weeks if necessary. Frequent lavage of the bladder with mercuriochrom, nitrate of silver, or potassium permanganate is an essential. Fulguration in some instances has caused considerable fibrosis and contraction of the organ. He disclaimed any advantage attending the use of deep roentgen

therapy or radium. The paper was profusely illustrated with colored plates.

"Chronic Cholecystitis," James A. Guilfoil, who emphasized the importance of the pathological work done by Graham, Heyl, MacNeal, McCarthy, and others in promoting our knowledge of cholecystitis, its sequelae and treatment. He stated that cholecystitis is always accompanied by hepatitis, which may be primary or secondary, through extension by the lymphatics, and further extension may be productive of choledochitis and pancreatitis. A vicious circle may be established in the maintenance of two or more of these lesions. Owing to the position of the liver in the blood vascular system, it may be affected by infectious and toxic agents carried by the arterial and portal channels. It has been established that there is a relationship between gastric and duodenal ulcers and appendicitis, and cholecystitis, but there undoubtedly exists also a relationship between focal infections (teeth, tonsils, sinuses, rectum, and prostate) and cholecystitis, the infectious, toxic agents, or both being carried thereto by the blood stream. Many cases of hepatitis, with or without cholecystitis, will subside with appropriate measures directed toward the primary focus of infection, together with the establishment of a suitable diet.

"Roentgen Demonstration of Cholecystitis," Frederick H. Rodenbaugh. Roentgenologists have been much interested in extending the diagnostic field of the alimentary tract from organic to functional disturbances and the recognition of the fact that diseases of the biliary system produce profound disturbances of the gastro-intestinal functions, will be a great help in the diagnosis of these important diseases. Dr. Rodenbaugh also believes in the associated hepatic pathology and stated that the appreciation of the role played by focal infections in producing biliary-tract diseases might do much toward the treatment of these biliary disorders.

St. Joseph's Hospital Discusses Post-operative Complications—St. Joseph's Hospital staff, San Francisco, considered "Post-operative Complications" on February 11, A. S. Musante and W. T. Cummins presiding in turn. A. W. Hewlett spoke on "Medical Post-operative Therapy," summarized as follows:

The treatment of post-operative pneumonia has not altered in recent years. The various improvements suggested from time to time have later been discarded, so that we must still depend on the methods used twenty years ago. The advances in our knowledge of heart disease have a bearing on post-operative problems. Heart disease seldom is an absolute contra-indication to operation—rather it increases the hazard. If the operation is imperative, the chance must be taken. If the operation is one of choice, the increased hazard must be considered by the surgeon before he decides. Most serious are the signs of failing circulation—pronounced dyspnoea, distended veins, swollen liver, albuminuria, and edema. Of cardiac murmurs, the systolic in themselves can be disregarded, while the diastolic—whether of aortic insufficiency or of mitral stenosis—are always serious. Of irregularities, extrasystolies in themselves are inconsequential, but auricular fibrillation is more serious, and a preliminary course of rest and digitalis should be given if the heart rate is rapid. Chloroform should not be used if there is cardiac disease. The occasional sudden cardiac deaths in the early stages of anesthesia are due to ventricular fibrillation, which is more apt to occur when chloroform is used. In these overdoses epinephrin, intravenously, may be tried; also cardiac massage from beneath the diaphragm if the abdomen is opened.

Circulatory failure after operation is usually due to hemorrhage or shock. In either case not enough blood returns to the heart to enable this organ to maintain the circulation. Most important is the administration of large quantities of liquid. Salt solution by rectum or subcutaneously is required and, in case of emergency, intravenous injections of liquid. Gelatine, acacia, and glucose (10 per cent) solutions or whole blood may be used, but the reaction with chill is a disagreeable and sometimes dangerous sequel. Epinephrin is valuable, but transient. Tyramin hydrochloride in doses of 0.04-0.08 every 20 to 30 minutes will sometimes rescue an apparently hopeless case. Strychnine and camphor are useless. Caffeine is of doubtful value.

Cardiac failure is difficult to differentiate from shock. In some instances an abnormal rhythm, such as auricular flutter or fibrillation, calls for rapid administration of digitalis. Paroxysmal tachycardia may sometimes be checked by vagus pressure. As a rule, where cardiac failure is suspected, digitalis should be rapidly given. Intravenous injections are dangerous and are to be avoided. If no digitalis has been given previously, a dose corresponding to from 12 to 16 cc. of the tincture, according to weight, should be given immediately. Absorption from the rectum is as rapid as orally. Subcutaneous injections are effective, but painful. These large doses should not be repeated. They become effective in two to six hours. At present it is difficult to estimate the value of digitalis in post-operative circulatory failure, but our knowledge of the drug indicates that only large doses can be expected to be beneficial.

Dr. C. A. Walker spoke on "Post-operative Surgical Complications," abstracted below:

Careful attention to pre-operative, operative, and post-operative details will prevent or make one anticipate later complications. Complications may be immediate, intermediate, or remote; e. g., a hemorrhage almost immediately after an intestinal obstruction within one to two days or obstruction even months later from adhesions.

Post-operative Hemorrhage—Primary type begins at operation and continues for some time, suggesting a blood dyscrasia. Reactionary type appears often when consciousness is returning and may be due to a ligature slipping. Secondary type shows up later, often in wound infections and arteriosclerotics. Symptoms, according to rapidity and amount of bleeding, are a quick, short cry, rapid, weak pulse, subnormal temperature, air hunger, thirst, impending feeling, pale, clammy skin, restlessness, dilated pupils, and collapse. Treatment includes prophylaxis, checking bleeding and preventing its recurrence, and aiding recovery. Morphine and replacement of lost blood by transfusion of whole blood, or acacia, normal or hypertonic salt, gelatin (1 to 2 per cent in saline), and Hogan's solutions are used—cautiously with unligated vessel. Elevate the feet. After treatment for secondary anemia is needed. Locally, apply clamp and ligature and, if small or persisting bleeding, iodoform packs. Hot water, extreme cold, caustics, and thromboplastin may help. Slow oozes may be stopped by subcutaneous horse serum, coagulin and other coagulants.

Post-operative infections may remain localized, spread to contiguous parts or cause parotitis, empyema, septicemia, etc., and treatment must be accordingly. In gas bacillus and tetanus infections use free incisions and remove necrotic tissue. Anti-tetanic serum is potent.

Post-operative ileus and the more readily amenable and transitory pseudo-ileus must be differentiated. True ileus has septic and mechanical types—former from peritonitis and later from angulation of bowel. Ochsner treatment, overcoming of dehydration, gavage, establishment of fecal fistula are indicated for septic form and relief of obstruction and correction of cause in mechanical type, though palliative enterostomy may be best at first. Post-operative disruption of wound, sinuses, and fistulas are not uncommon and demand appropriate treatment.

Alex Keenan and P. Collischonn discussed the topic, and R. M. H. Berndt and William Quinn presented case histories, respectively of nephritis-carditis, with Cheyne-Stoke breathing long before death, and influenzal (pneumococcal) meningitis, lasting forty-five days.

The program for March 11, "Medical Economics Night," follows: "Approved Investments for Doctors," Percy A. Woods; "Best Methods of Handling Doctors' Accounts," Attorney J. F. Denman; and "The Doctor as a Better Business Man," C. A. Mariani.

The San Francisco Polyclinic—At the annual meeting held recently, President H. A. L. Ryfkogel announced that the clinic served 35,000 ambulatory patients free of charge during the last year.

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by Alex C. Soper Jr., secretary)—Thirty-four members, with the six house officers of the Cottage Hospital, Mr. Curtis the superintendent, Dr. Charles F. Mills, president of the San Luis Obispo Society, and Drs. B. E. Merrill and C. E.

Schultz of Santa Paula as guests, assembled at the Hotel Carrillo January 12 for the annual banquet.

Addresses were made by Drs. L. W. Hotchkiss, H. F. Pierce, Allen Williams, Franklin Nuzum, and Henry J. Ullmann, on various and sundry subjects, some of them serious, some of them humorous. Dr. Samuel Robinson, the president, held down the chair.

The banquet was succeeded by a series of moving picture scenes taken by Dr. Ullmann, first of which was a procession of staff doctors leaving the Cottage Hospital, and second, a comic section devoted to the antics of "Felix the Cat." Drs. Robinson and Soper had also prepared some caricature of the idiosyncracies of certain members of the society, which, in the form of lantern slides made by Dr. Ullmann, were put upon the screen.

The election of officers for 1925 resulted in making Franklin Nuzum president; H. E. Henderson, vice-president; and E. D. Smith of Solvang and O. C. Jones of Lompoc, vice-presidents-at-large. The secretary-treasurer was re-elected. The election of delegates to the state convention was postponed, due to the late hour. No action was taken on the dues for the ensuing year.

Santa Barbara County Medical Society Meeting, February 9, 1925 (reported by Alex C. Soper Jr.)—This meeting was held at the Cottage Hospital, with President Nuzum presiding. Present, nineteen members, one interne, and Dr. Hagen of the house staff, as well as Dr. Allen, president of the County Dental Society.

Moved, seconded, and passed that the censors of the ensuing two years be appointed by the Chair. The president reserved action for consideration.

Moved, seconded, and passed that the annual dues be the same as in 1924, namely, \$12 for both county and state.

Henry J. Ullmann was elected delegate for the state convention, with William J. Mellinger as alternate.

Communication regarding the Gorgas Memorial Fund was, by vote, laid on the table.

Letter from the State Board of Health regarding examination of school children reported, and the secretary instructed to reply. Another from the board, in re incidence of endemic goiter, to be answered in due time, after asking each member of the society, through question inserted in the notices of meetings. In this connection, W. D. Sansum reported briefly on evaporation—analysis of waters in the vicinity supplying the community, stating that the city supply gave fifteen parts; Montecito, 8000; and a private well 400 of iodine—according to work recently done at the hospital.

A letter from a member, calling attention to the frequent appearance of press reports of physicians giving lectures to the laity, and asking for a discussion of the subject, brought out considerable talk pro and con. The consensus of opinion was finally to take no action in the matter, since the state society emphasized the value of such lectures outweighing the advertising of quacks, if given by physicians of standing in the community, whose names necessarily added weight to their subject matter.

The paper of the evening was by Joseph D. Lewis, M.D., Santa Barbara, on "Neoplasms of the Larynx," illustrated with lantern slides. This long and interesting exposition was discussed thoroughly by Schurmeier, Freidell, Ullmann, Means, and Profant.

✽

SONOMA COUNTY

Sonoma County Medical Society (reported by G. A. Hunt, secretary)—The first regular meeting of the year was held in the Hotel Petaluma, in Petaluma, January 8. Thirty members and four guests were present. A duck dinner preceded the regular meeting.

Doctor V. H. Podstata, superintendent of Livermore Sanitarium, gave an interesting and instructive address on "Psychotherapy and General Medicine." Few speakers have been more thoroughly appreciated than Doctor Podstata. It may be that doctors feel their need for psychotherapy as well as their patients.

NEW HEALTH OFFICERS APPOINTED

Ernest Dozier, M. D., of Redding has been appointed health officer of Shasta County, succeeding Sherman T. White, who has occupied the position for many years. Doctor Dozier is licensed to practice medicine in Cali-

fornia, and is a member of the California Medical Association.

Alex M. Lesem, M. D., has been appointed city health officer of San Diego, succeeding George B. Worthington, M. D. Doctor Lesem is also county health officer for San Diego County. He is licensed to practice medicine in California, and is a member of the California Medical Association.

Carl P. Jones, M. D., health officer of Nevada County, has recently been appointed city health officer of Grass Valley, to succeed Paul D. Barnes, M. D. Doctor Jones is licensed to practice medicine in California, and is a member of the California Medical Association.

Alfred L. Phillips, M. D., has been appointed health officer of Santa Cruz County, to succeed W. H. Keck. Doctor Phillips is licensed to practice medicine in California, and is a member of the California Medical Association.

CHANGES IN MEMBERSHIP

Deaths

Bacon, Charles Evan. Died at Los Angeles, February 4, 1925, age 60. Graduate of Kansas City Medical College, 1890. Licensed in California in 1898. Doctor Bacon was formerly a member of the Los Angeles County Medical Society, the California Medical Association, and the American Medical Association.

Franklin, Berte Vosburgh. Died at San Diego, January 16, 1925, age 50. Graduate of the University of Southern California College of Medicine, Los Angeles, 1901. Licensed in California the same year. Doctor Franklin was a member of the San Diego County Medical Society, the California Medical Association, and the American Medical Association.

Harry, Charles Rees. Died at Stockton, February 6, 1925, age 62. Graduate of Cooper Medical College, San Francisco, 1890. Licensed in California the same year. Doctor Harry was a member of the San Joaquin County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Nichols, Albertus Bentley. Died at Oakland, February, 1925, age 46. Graduate of the College of Physicians and Surgeons, Maryland, 1904. Licensed in California in 1921. Doctor Nichols was a member of the Alameda County Medical Society, the California Medical Association, and the American Medical Association.

Smith, Thomas Hardy. Died at Pomona, February 10, 1925, age 70. Graduate of the Washington University Medical School, St. Louis, 1882. Licensed in California in 1888. Doctor Smith was a member of the Los Angeles County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

NORMAN BRIDGE, M. D.

1844-1925

Coming to Los Angeles nearly thirty-five years ago, Doctor Norman Bridge soon won for himself a place of distinction, not alone in the medical profession, but among his fellow-citizens.

Having been for many years professor of medicine in Rush Medical College, much work in medicine was referred to him by graduates of that institution, and his practice soon grew to dimensions that required all his physical strength. For a number of years he returned to Chicago to continue a three months' course of lectures at Rush.

In later years he became interested in the Mexican Petroleum Company, after making several trips to Mexico, and his work in this line gradually extended until during the last few years it had absorbed most of his time.

His writings along medical lines have been extensive. In addition to this he has written a number of volumes on other topics. One of his latest works, "Marching Years," is a modest and fascinating autobiography.

His interest in educational affairs has been such as to lead him to become a most liberal contributor to several institutions of learning—notably the California Institute of Technology and Rush Medical College. His philanthropies have been many and varied; the great majority of which have been known by few of those most intimately acquainted with him. In short, it may be said that

NORMAN BRIDGE, M. D.

his great life work has been along those lines conducive to the uplift of humanity.

But it is to those most closely associated with him that the true dignity of a most noble and elevating character, free from guile and the foibles of ordinary men, can be most fully realized and comprehended. Charitable as to the opinion of others, but firmly true to his own convictions, undeviating in the course of righteousness to God and fellow-man, unflinching in staunchness for the right of all things, he has always been an example worthy of emulation by those associated with him. Legions mourn his loss and realize that a strong, brave, noble character has passed out from our material presence and to his reward.

There are too few such characters in the world, and all who have had the fortune to be closely associated with him have been lifted to a better life than had they not been recipients of his friendship.

GEORGE L. COLE.
ANDREW STEWART LOBINGIER.
HENRY W. HOWARD.

STIMULANTS, DEPRESSANTS, HUMOR

"Shall We Pray?"—Louise Collier Willcox's answer to this question (Harper's) is "good medicine" for many a weary one.

"No arrow is shot but hits somewhere; no song is sung but echoes on in someone's heart; no pebble falls but the stars tremble."

1-19—Of the 87,000 babies born in California in 1924, one of each nineteen of them is scheduled to die of cancer, unless they grow up with a higher order of intelligence than has this generation.

Garlic as a Deodorant?—Try as we may, we cannot follow the "scientists" who are now widely advocating the virtues of garlic as a deodorant: so we notice it here.

"Eventually"—The victim of the quack eventually reaches the physician; and when he does, it is usually

with a condition which has arrived at the chronic stage and which requires prolonged treatment for a cure—even if a cure be possible at all.—S. J. Kopetzky, President New York Medical Society.

Professor—And what did the poet mean by "Wind Along the Waste?"

Practical Pre-Med.—Gas on the stomach, I guess.

"Should evening clothes ever be worn at bridge parties?"

"No, in playing cards it is only necessary to show your hand."

Dear Doctor—I have your letter returning my manuscript, and frankly say to you that I have been mistreated in this matter. I desire that you know that I resent this, and from now on you need not call upon me for any paper or other help, and I shall leave the State Society, retaining my fellowship in the American Medical Association by virtue of my commission in the army.—X., Los Angeles.

Some Consequences of "Health Education"?—One physician reports that a young woman patient consulted him about her "orgasmus retardatus"?! Another patient consulted her physician about her "anomalous sex life," which was caused by her husband's "ejaculatio praecox"?! Every doctor can tell incidents of this type that are "new" and are always directly traceable to the so-called health education.

Real health education by competent teachers is as commendable as it is old, but we are only beginning to see the consequences of much that goes by the name of "education."

Because your wife is forty is no sign you can exchange her for two twenties.

Sons—This is the title of a short story by B. H. Lehman (Harper's) that has a moral, several lessons and heart throbs that every doctor will enjoy.

A Glanded Car

A negro was up before the judge on a traffic charge.

"Black boy, how fast were you traveling?"

"Wal, jedge, I reckon it was close to seventy-fo' miles an hour."

"Nigger, what kind of a car do you drive?"

"A Ford, sah."

"Boy, don't you know that no Ford will go that fast?"

"Jedge, yo jess doan' understan'; dis Ford am different—it's got Packard glands."

Enclosed herewith is my discussion of Doctor —'s paper, and with it please accept my apologies for the delay. I shall never let it happen again.—Dr. —, San Francisco.

Too Much Steam—They were discussing a certain undefeatable and irrepressible politician.

"Well," summed up the smoke-room philosopher, "I'll tell you this about him. He might have typhoid and recover; he might have pneumonia and recover; he might have yellow fever and recover; but—if he ever had lock-jaw, by gad, he'd bust!"—The Doctor.

There is as much policy as there is ethics in withholding the names of physicians from public print which records their sayings and doings. The profession as a whole will harvest more of the fruits of publicity by allowing its lay advocate to hold up before the public achievements that speak for themselves and by permitting the public to construct its own argument.—Bulletin San Diego Medical Society.

Osteopathic Literature—"Exercise, air, rest, water, natural eats, and an osteopathic doctor make for life, health, and prosperous days."

"Ashes to ashes, and dust to dust;
If the Medics can't fixe me, the
Osteopaths must."

CALIFORNIA ACADEMY OF MEDICINE

At the first meeting of the year, held at a dinner at the Palace Hotel January 24, the following officers were elected to serve for the calendar year 1925: President, Herbert C. Moffitt; vice-president, William Ophuls; secretary-treasurer, J. Marion Read.

The president has appointed the following executive committee: Harold Brunn, R. Knight Smith, Morton Gibbons, E. W. Twitchell, A. W. Hewlett, Elbridge J. Best.

All communications should be addressed to the newly elected secretary-treasurer, J. Marion Read, at 870 Market street.

Utah State Medical Association

SOL G. KAHN, Salt Lake City.....President
WILLIAM L. RICH, M. D., Salt Lake.....Secretary
J. U. GIESY, 512 Felt Bldg., Salt Lake City,
Associate Editor for Utah

NEVER TOO OLD TO LEARN

We imagine that if our grandfathers, who were perchance physicians, could live today and enjoy the facilities of diagnosis and practice now at our disposal they would burst into tears of delight.

The diagnostic laboratory, the x-ray, more modern and standard methods of examination and history taking, have in a measure revolutionized the work-up of the average case with which we come in contact, though heaven knows some of those old boys were bears at physical examination and seemingly carried eyes in their finger-tips.

Be that as it may, times change, and we ought to change with them. Nowadays the average patient is from Missouri, no matter where he was born, and it is high time that we adopted the Missouri standard among ourselves.

Never too old to learn is a motto every doctor ought to pin in his hat or over his desk, or somewhere, capable of being seen at least daily. It's a sort of preventive from falling into a rut. And ruts are bad things, on a road or in a practice. Today more than ever we should be vigilant. There is just one thing of real interest to the patient and that is—the end-result.

Therefore, we should learn, and keep on learning, and in every community with three or four medical men there is a ready means to this end. Get together—organize a "Review Class." Meet once a week or every two weeks and compare notes, review current literature, write up some interesting subject or case and read it together and discuss it after that. Friction brightens even while it grinds. This is as true of mental processes as of machinery, and if you don't believe it try the experience of going up against some confrere who knows more about a given matter than you do and see if it doesn't—grind! It will, but it will brighten at the same time—it will prove a mental stimulant.

The writer has had the privilege for some years of attending such a class. It has done more than any one thing to help him to keep at least in touch with the profession, and not entirely lose step. There is only one time when a doctor knows it all and that is the first week after he graduates. After that he will, if normal, admit a sense of bewilderment as to just how the men who passed him into the field of medicine happened to make such a whopping mistake. No, we're never too old to learn. So let's get busy learning. And there is no better way for the average man than to organize or gain admission to some already organized review class.

Incidentally, every man in Utah who can make the grade ought to begin now to prepare to attend the session of the Utah Association at Salt Lake in September, and to remain long enough to avail himself of the excellent program being arranged for the immediately following course in post-graduate work.

Utah Hotes (reported by J. U. Giesy, associate editor)—The dates for the Utah Medical Association meeting to be held in Salt Lake City have been definitely set as September 7, 8, and 9, and on September 10, 11, and 12. A course in graduate instruction will be held for all physicians attending the meeting who may desire to avail themselves of the opportunity of enjoying the excellent program now being arranged.

Thus far Doctors Hamaan of Cleveland, Ohio, surgeon; Walter T. Williamson, chairman of the board of trustees of the A. M. A. of Portland, and Brassch of Rochester, Minnesota, have promised to be on hand. Other names are on the list of possible available lecturers now being corresponded with by Doctor Frank Steel, who has this part of the arrangements in hand.

Governor George H. Dern and Health—Instead of following the usual custom of discussing finance and politics in his inaugural message, Governor Dern of Utah secured extensive nationwide publicity because he chose health as his subject. The doctors of Utah are much pleased at having their work thus recognized in a way that will produce wholesome results.

Shriners' Hospital for Crippled Children Opened—The entire south wing of St. Mark's Hospital, Salt Lake City, has been leased by the Shriners and remodeled as the Salt Lake unit of their hospitals for children. The Mystic Shrine has erected six hospitals exclusively for children, and the seventh is in process of construction. In addition, in smaller communities, half a dozen such havens for crippled children have been opened—as the one in Salt Lake. As is the case with the other hospitals supported by this mystic organization, this unit will be devoted to the care of the sick children of Utah. A. L. Heuther, M. D., has been appointed head of the institution. Miss Mabel Torgeson has been appointed day superintendent and Miss Nena Williamson, night superintendent.

Recent Admissions to Practice Medicine in Utah—Results of the recent examinations for student pharmacists, physicians and surgeons were announced recently by J. T. Hammond, state director of registration.

Vernon F. Houston of American Fork, N. Henry Savage of Ogden, C. R. Cornwall of Salt Lake, A. L. Huether of Salt Lake, E. L. Christensen of Salt Lake and Norman Olsen of Salt Lake, who took the examination for physicians and surgeons, will be granted licenses. All of the persons who took the examination passed.

R. G. M. Ehlers was granted a physician's and surgeon's license through reciprocal agreement with the United States Army. Others who will be permitted to practice in Utah because of such arrangements and the states in which they had been licensed, follow: L. E. Gowney, Nebraska; C. A. Parker, Kansas; David Maeth, New York, and Nelson Adam Young from Minnesota.

J. T. Hammond, state director of registration, announced that he received \$1150.50 in fees last month.

Doctor Murray Rockwell Stewart, City Commissioner, died recently, following an illness extending over a period of two weeks.

Dr. Stewart was a member of the Salt Lake County Medical Society and of the Salt Lake Chamber of Commerce. He was elected to the city commission more than three years ago, and was head of the department of parks and public property.

His parents are both dead, the only surviving relatives being his widow, Mrs. Nellie Walker Stewart of this city, and his brother, Charles T. Stewart.

Box Elder County Medical Society (reported by W. Leroy Smith, secretary)—The Box Elder County Medical Society met January 28 in their annual meeting, and elected the following officers: President, R. A. Pearce, Brigham, Utah; vice-president, T. E. Betensen, Garland, Utah; secretary-treasurer, W. Leroy Smith, Brigham, Utah. Delegate to the State Medical Association meeting, Odeem Luke, Tremonton, Utah. Alternate, R. A. Pearce. Board of censors, E. A. Weymuller and E. H. White.

These were the same officers that presided the past year, they having given such satisfactory service in establishing the new society in our county, that it was the

unanimous opinion that they should continue another year to give the organization a good start.

During the past several months that we have been organized, we have had two luncheons that were well attended, and we have had three meetings at which excellent papers have been prepared and read by the members. One paper by R. A. Pearse on carcinoma of the breast was most interesting. The essayist gave an enthusiastic report of the numerous cases, and illustrated the great amount of increased suffering that is always caused by operating on an inoperable carcinoma that has metastases far from the original tumor, presenting histories of such cases. Another paper by Odeem Luke on the relation of the general public to the present publicity given to venereal diseases and their prophylaxis opened up general discussion of the subject, as it applies locally with very promising effect. And at the last meeting E. A. Weymuller gave a very good paper on some of the minor details in acute and chronic endocarditis.

The members of the society all feel that the meetings have been very beneficial and the attendance has been good, although some of the members have long distances to travel. This difficulty has been overcome by having some of the meetings at the outside points.

Salt Lake County Medical Society (reported by L. J. Paul, acting secretary)—A meeting of the society was held January 26, at the Holy Cross Hospital, Salt Lake City. President John Z. Brown presided, with 49 members and 19 visitors present.

Four clinical cases were presented.

Applications for membership by Leland R. Cowan and Ralph M. Tandowsky were read and referred to the board of censors.

The meeting was then turned over to M. M. Nielson, chairman of the Holy Cross Hospital program committee. A. A. Kerr presented two clinical cases showing successful skin grafting, and discussed a case of acute purulent infection of the gall-bladder. Wilford W. Barber presented and discussed a case of coeliac disease and a case of intermittent subacute intestinal obstruction. The cases were discussed by Root, Stevenson, Tyree, and Brown. John W. Sugden discussed a clinical case and presented post-mortem specimens showing congenital polycystic kidneys. H. P. Kirtley discussed a clinical case of acute prolapse of the uterus in a primipara with forward displacement of "sixth" lumbar vertebra. Specimens were presented, and discussion given by H. P. Kirtley on a case showing absence of a cervix, as well as an absence of opening into the uterus in a patient of 23 years. W. G. Schulte discussed a case showing the value of pyelograms in nephrolithiasis.

The applications for membership of Alfred Blumberg and J. E. Day, having been favorably reported by the board of censors, were accepted by formal vote by the society.

The following committees were appointed:

Medical Liability Insurance Committee—F. A. Goeltz, chairman; Sol G. Kahn, S. D. Calonge.

Medico-Legal Committee—E. F. Root, chairman; H. P. Kirtley, J. C. Landenberger (three years); A. C. Behle, S. H. Allen, W. S. Ellerbeck (two years); M. C. Lindem, C. L. Shields, F. Leaver Stapffer (one year).

Following the meeting, the Sisters of the Holy Cross Hospital served apple cider and wafers.

Salt Lake County Medical Society Meeting of February 9, 1925—A regular meeting of the society was held February 9, at the Commercial Club, Salt Lake City. President John Z. Brown presiding. Members present, 48. Visitors, 3. No clinical cases.

Clinical Program—Frank B. Steele read a very interesting and instructive paper on the treatment of pneumonia, mainly taken from his own practice, corroborating much of the work reported in the literature. Discussion opened by Perry G. Snow and L. W. Snow.

John F. Sharp discussed very effectively the principal complications of pneumonia from the surgical standpoint, stressing especially the treatment of empyema. He contrasted the opened and closed methods of draining the empyema cavities. He strongly advocates the closed method, which he described in detail, presenting a case on

which both methods had been used. Discussion by Roy Groesbeck.

A letter from our oldest honorary member, Salathiel Ewing, thanking the society for the birthday remembrance to him which he stated was very, very much appreciated, was read.

Report of the medico-legal committee on the case against Spencer Wright was given by Chairman E. F. Root.

The following new members were elected to the society: Leland R. Cowan and Ralph M. Tandowsky.

Nevada State Medical Association

W. M. EDWARDS, M. D., Mason.....President
CLAUDE E. PIERSALL, M. D., Reno.....
Secretary-Treasurer and Associate Editor for Nevada

Nevada Notes (reported by C. E. Piersall, associate editor)—The staff of the Elko General Hospital met at the hospital staff rooms on January 13. The following officers were elected for the year 1925: Chief of staff, J. R. Eby; vice-chief of staff, C. E. Secor; secretary, John E. Worden.

Immediately following the staff meeting, was the meeting of the Elko County Medical Society, which was called to order by the vice-president, J. R. Eby. The officers for the year 1925 were elected, and are: President, A. C. Olmstead; vice-president, J. R. Eby; secretary-treasurer, John E. Worden.

Washoe County Medical Society (reported by Henry Albert, secretary)—The society met in regular session in the rooms of the Chamber of Commerce February 9, President Muller presiding.

Program—Dr. Henry Albert presented a brief report on "The Immune Reaction to Smallpox Vaccination." Paper was discussed by Pickard and Morrison.

The paper of the evening was by C. P. Caples on "Genito-urinary Tuberculosis." Discussion by Lewis, Morrison, and Albert.

New Business—M. A. Robison presented a draft of a bill to create a state bureau of health in a department of public welfare. On motion, this was referred back to the committee for revision and resubmission at some future meeting.

Doctor Robison also referred to the County Hospital Bill. On motion, the following committee was appointed to assist in securing the passage of said bill through the legislature: Robison, Chairman, Robinson, Pickard, West, Morrison, McLean, and Caples.

Robison also referred to the following items, which are before the legislature for consideration: (1) To change the word "misdemeanor" in the Medical Practice Act to "gross misdemeanor." (2) To change the word "may," referring to revoking a license to practice, to "shall." (3) To prohibit the sale of paregoric and certain other drugs except on a physician's prescription.

There was a general discussion of the control of transmissible diseases. Dr. Samuels offered the following motion: That a committee be appointed to confer with the County Commissioners within twenty-four hours if possible, and demand that the County Isolation Hospital be put in proper condition to receive all kinds of communicable and infectious diseases at once, and that the results of the interview with the County Commissioners be published in both of the city dailies as paid advertisements, and that the bill for same be paid by the Washoe County Medical Society. Passed.

The following committee was appointed: Samuels, chairman, Pickard, Morrison, West, and Tees.

Attendance—Adams, Albert, Brown, Caples, Fuller, Lewis, Morrison, Muller, Pickard, Piersall, Robinson, Robison, Samuels, Stadherr, Thompson, Tees, Walker, and West.

Medical Economics and Public Health

A Sane and Just Appeal—A case sufficiently suspicious to call for antitoxin is suspicious enough to be reported to the health officer for isolation and investigation of contacts for possible carriers. Without such co-operation on the part of every physician, no health department can ever hope to eliminate the disease from the community.—John J. Sippy (California Health Bulletin).

"Economics teach the biologist that the prolongation of life beyond the age of effectiveness is a perversion. Man should be a contributor to the dynamics of his community and not a burden," says N. Philip Norman, M.D. (New Jersey Medical Journal). "On the other hand, there can be no doubt of the biologic desirability of increasing the health span of the individual and ultimately that of the race."

A. M. A. Bulletin—Don't forget, doctor, that the Bulletin of the A. M. A., which goes to every member free, is the most useful medical publication in existence. No doctor can afford not to read in its entirety the January, 1925, issue. It is easy reading, and the matter is of the utmost importance. The authors, for the most part, are those we have elected as our leaders. Harken to what they say.

Nourishing, Well-Balanced Diet for Thought—Wouldn't it be possible for you to be a little more simple when you come into the sick-room and use a vocabulary, even if it is somewhat of a strain, of words that can be found in a comprehensive dictionary, and, in telling the patient what is the matter with him, to try to do it in language used in the home? . . .

When you come to my house and I have a sick child and you sit down and lay out the things that you want us to do, may I be bold enough to suggest that you do what the quack doctor does—leave a little literature. Not only is my understanding feeble, but my memory is short. If I have a child with measles, the sixteen-page booklet of the American Medical Association, costing 5 cents, might be left at the house; it only costs you a nickel, and you are going to take away \$150.—Will B. Forbush, Ph.D. (Long Island Medical Journal).

Selling Indirect Service—There is a great tendency today, which is growing very rapidly, for this personal or direct service to be interfered with by commercial organizations, to be taken away from the individual physician by a corporation rendering to the individual an indirect service. By indirect service I mean a service based on what information someone else may get from the person who is in actual contact with the individual. It is perfectly evident, it seems to me, that any such indirect service is to the detriment of the welfare of the individual, *because it can never be as valuable to him as a like service rendered personally.*

These organizations claim that they are not dealing with the sick, but only with the well, and that their service is not the practice of medicine. In the very next breath, in order to show the necessity of their business, they claim that 97 per cent of those whom they examine are not well, that they have some physical defect or some disease which has not been recognized by reason of the fact that the individual has never been examined, and it is their duty to be the intermediary between the individual and the medical profession. I never knew that the medical profession needed a go-between.

They not only have these individuals examined, but they say they amplify the knowledge which they get from the doctor, just like speaking through a megaphone, and that the description sent in by the doctor is muddled over by a number of individuals who have not seen the patient and know nothing about him except what has been told them, and that that has greatly increased the value of the physician's examination. In other words, A REAL EXAMINATION BY THE INDIVIDUAL WHO HAS PERSONAL CONTACT

WITH THE ONE EXAMINED IS WORTH SEVERAL TIMES AS MUCH AFTER IT HAS BEEN TRANSMITTED TO SOMEONE WHO HAS NEVER SEEN THE PATIENT.

These institutions not only tell the individual what the matter is with him, but acknowledge that they advise him as to his diet, as to his exercise, and as to the type of medical treatment which he should seek. If diagnosing the case, advising as to the hygienic measures, diet, and any medical treatment which they might think he needs is not practicing medicine, none of us is engaged in the practice of medicine.

Some of these institutions claim that they are not commercial, and that the motive back of them is purely altruistic, but to show that the commercial idea has not been lost sight of, one of them is going to start branches in at least one new state in the near future, and already has started a branch in one state. It is negotiating for a branch in another state; and its method of creating these branches, as I understand, is through the sale of stock, 7 per cent preferred stock. It is to be presumed that the profits from the work will furnish ample means to pay 7 per cent interest on the stock issued. If that isn't a purely commercial proposition, it would be difficult to find one. The idea seems to be to sell a part of this preferred stock to certain doctors in the neighborhood, who would thereby become a part of this organization and help it along.

The service furnished is an indirect one, and any indirect service to an individual is not furnishing him the kind of service to which he is entitled and for which he pays. That can be only a personal and direct service.—M. L. Harris (A. M. A. Bulletin).

"Must the Doctor Answer a Call?"—"The following," concludes Joseph J. Lilly of the New York bar (Medical Economics), "may be stated to be the rules which govern the initiation and termination of the relation of physician and patient:

"1. The physician is under no legal obligation to accept and care for a patient, no matter how grievous the necessity of the patient may be.

"2. If the physician accepts the patient, only for temporary care, as e. g., where he gives immediate treatment to the sufferer from an accident, he should make it clear that further treatment will have to be given by another physician.

"3. The patient may discharge the physician at any time, and from the moment of the discharge the physician is relieved of all liability for future care or treatment.

"4. The physician and the patient may agree to terminate his employment.

"5. The physician may of his sole election terminate his employment, provided timely notice, according to the particular circumstances of the case, be given to the patient to procure another doctor.

"6. When the condition of the patient is such that further medical attention is no longer necessary, the physician may discontinue his services, but should, of course, so advise the patient."

New York Is Attempting to Put This Into Their Industrial Accident Law—It shall be the duty of every employe or applicant for employment in any of the employments enumerated herein:

1. To submit himself to medical examination as herein provided.

2. To furnish true information to his employer or prospective employer regarding his past employment in the employments enumerated herein. The industrial board shall, if necessary, make rules for carrying into effect the provisions of this section.

From One Who Ought to Know—As a result of the indifference of the average pediatrician to child welfare work, his domain has been encroached upon by outsiders not trained in medicine, but keenly alive to the necessity and opportunity for this line of work. The social worker, the nutrition expert, and the public health nurse have entered in and in some instances monopolized the field. . . .

There is a feeling of distrust and perhaps jealousy on the part of some pediatricians toward the child welfare clinics. They learn that one of their little patients has

been taken to a child welfare conference. That the visiting nurse has followed the case in the home and that the mother has become a regular attendant. The family physician feels, and *justly so*, that he has lost a patient.—Henry L. K. Shaw (New York Journal of Medicine).

The Young Doctor and the Medical Society—Dr. Gordon S. Fahrni, in his presidential address before the Manitoba Medical Association, said: "Too little guidance is at hand for the young man just out of college who is suddenly thrown on his own resources. This association should at once endeavor to procure this man's membership, as we need his support and he may be in need of ours. I would, therefore, suggest to this meeting the advisability of giving membership to doctors during their first year's practice at half the regular fee, or even less. The benefit, I feel sure, would be mutual."

The director of the American Red Cross Association says that the principles that should be observed by every reputable health nurse are:

1. Public health nurses do not diagnose, do not prescribe drugs, and do not give treatment without a doctor's orders.

2. Public health nurses do not give nursing care after the first visit without a doctor's orders.

3. Public health nurses do not recommend individual doctors, but advise patients to go to their family physician.

4. Public health nurses do not recommend that patients change doctors or seek hospital care when they have a family physician.

These principles are highly commendable and probably have the endorsement of most nurses. The trouble is that many nurses are employed by and, therefore, take their orders from political bureaus and uplifters that consider the director of the Red Cross Association old-fashioned and out of date.

"Financial success that has its foundation based upon industry, efficiency, and the best kind of professional work is not only admirable, but it is and should be a source of healthy inspiration to all physicians," says Edward Beardsley (Journal of Medical Society of New Jersey). "An income from the medical profession, however, that is acquired as a result of, consciously or unconsciously, lowering one's professional ideals and, more particularly when gained at the potential sacrifice of the health of patients, as a result of careless and insufficient clinical study, is not to be envied."

Springing from a secretive priesthood, medicine for countless ages maintained a similar secretiveness, surrounding its activities with linguistic and other presumably imposing formalities. Some of that influence lurks about our work still—in our Latin prescriptions, in our nomenclature of disease processes, in our reluctance to enlighten the public, and in our star chamber consultations.—David Riesman (A. M. A. Bulletin).

Then and Now—When the British took possession of the Colony of New York, a law was promulgated by the Duke of York which forbade practice upon the people without the advice and consent of accredited physicians. Moreover, the consent of patients was conditioned as well. The object of the law was stated to be "to inhibit and restrain the presumptuous arrogance of such as, through confidence of their own skill or any other sinister respects, dare boldly attempt to exercise any violence upon or toward the body of young or old, one or another, to the prejudice or hazard of the life or limb of man, woman or child.

Here we are well into the twentieth century, and fond of assuming that we have moved very far along the path of social evolution, yet the law which we have quoted betokens a far higher civilization than our own.—Medical Times.

The private physician is more or less familiar with the patient's interests and environment and, therefore, better able to render health service to the individual than is the case when the examinee comes as a stranger to a strange physician. This is important—the success of a

health examination depends more upon the rapport between physician and examinee than does a diagnostic examination.—Long Island Medical Journal.

Fitting Health Departments into Medicine—"Preventive medicine and curative medicine should go hand in hand," believes George W. Duvall, M.D. (Medical Economics). "The all-important factor, insofar as a whole-time health department will become either an asset or a liability to the physicians of the community, depends on the training and spirit of its head—the health officer. *The health officer who carries a thermometer, hypodermic syringe, or who has need of narcotic and whisky prescription blanks, is clearly out of his field.* He has need of a stethoscope, but for indigents only. He has need of the bacteriological laboratory in his office, but not from the standpoint of diagnosis, unless called upon by the physicians. He is in the field of free clinics, but they must be conducted so that they will not reflect discredit in the minds of the men of the profession.

"The whole-time health officer is a public servant whose work is educational, with the power to enforce health laws and regulations, and who, while not subservient, assists physicians in maintaining personal and public hygiene, isolation, and quarantine."

Health is the wage-earner's working capital. It represents the surplus on the balance sheet of his life. When by carelessness, neglect, or indifference, he allows it to fail, he topples into physical bankruptcy. His few remaining human assets are in jeopardy, and the heavy liability of despair settles upon him.—Thomas V. Gould (Long Island Medical Journal).

Why Fee Schedules Won't Work—The range of skill, knowledge, and judgment in the medical profession is precisely that of the range of skill, knowledge, and judgment in engineering, in business, in law or in any other human occupation in which a high, low or mediocre degree of human intelligence may be brought to bear upon any given situation.

"The public should be free to choose anything from a Galen to a chiropractor, in accordance with advice given by a grandmother or through choice made after an investigation similar to that customary with trustees of estates when buying bonds," says Medical Review of Reviews.

When Doctors Really Get Busy—"The University of Colorado School of Medicine recently announced the opening of the Colorado Psychopathic Hospital. The bill authorizing this hospital was enacted in 1919, but the legislature failed to pass an appropriation for its construction. In order that the project might not fail at this point, the Colorado State Medical Society secured a sufficient number of signatures to a petition initiating a bill with an appropriation of \$350,000. This bill was referred to the voters in November, 1921, and approved by a majority of about 100,000.

"The hospital is located at Denver and is an integral part of the University of Colorado."

PRACTICAL THERAPEUTICS AND THE ART OF MEDICINE

Mr. Felix Lengfeld of the Lengfeld Pharmacies of San Francisco, Dr. Fred R. Fairchild of Woodland, Dr. Henry H. Lissner of Los Angeles, Dr. E. Paul Cook of San Jose, and Dr. William E. Musgrave, editor of CALIFORNIA AND WESTERN MEDICINE, comprise the group of alumni instructors for 1925 in the course on Practical Therapeutics and the Art of Medicine given at the University of California Medical School. This course was given during the spring semester of 1924, and was so successful it was deemed advisable to repeat it in 1925. In general, the instruction will be the same as that given last year, each instructor spending a week at the hospital, taking part in ward rounds, assisting in the instruction of the students, holding seminars, and giving one talk to the student body and house staff on some problem in Medicine.

"She that hath no children doth bring them up well," says an old English proverb.

CORRESPONDENCE

AFRICAN ARCHERY NOTES

This is the first of a series of letters to California and Western Medicine from Saxton Pope, unfolding the "romance" of hunting Big Game in Africa with the bow and arrow. Those who have read Pope's delightful book, "Hunting With the Bow and Arrow," have gained an added respect for these primitive weapons in capable hands, and will look forward with eager anticipation for the exploits of this group of famous hunters.

Dear Dr. Musgrave—By the time this appears in print we shall be sailing over the briny deep on our way to the Big Game Hunt in Tanganyika, and at your request I start a series of periodic reports of our experiences.

This adventure is part of a sabbatical year, which I have taken to celebrate my twenty-five years in the practice of medicine—the theory being that a man should take his long dreamed of holiday when he can enjoy it and not wait till physical incapacity and loss of interest in life settle upon him. Usually a doctor waits so long that he takes his vacation in a wheel-chair, with a clinical chart carried at a convenient distance by a trained nurse.

So it might be said that I felt so well, I just had to go to the mountains, for I started, as all good Californians should, by seeing America first. Six months of this sentence was spent exploring in the mountains and hunting with my bow and my dog. Part of the time I was with Captain Cassius H. Styles, U. S. A., late of the Aviators Corps; part with Tom Murphy, the bear hunter, or Monte, the Klamath Indian, and part with Stewart Edward White, the author.

Mr. White became converted to archery after reading my famous book, "Hunting With the Bow and Arrow," and he has grown rapidly into an accurate shot. Already we have hunted geese, deer and bear together, and it is through his insistence that we journey to Africa to add glory and honor to the bow.

So, at the special invitation of Leslie Simson, who is now in British East Africa, Arthur Young, Mr. White and I go to join him on a safari into Tanganyika, an unexplored portion of what was German East Africa.

We leave New York March 6, sailing for Cherbourg, France. From Marseilles we embark upon the Mediterranean and go through the Suez Canal, Red Sea, into the Indian Ocean, landing at Mombassa. From here we take the train to Nairobi, Kenya Colony, at which point we motor in Ford cars over the open plains for three days' journey south near Lake Tanganyika. From this point we go on foot with native packers into the jungle.

This requires six weeks' travel, and we expect to be gone six months, hunting. Our object is not of scientific interest—it is purely a romantic adventure. It is true that Doctor Terry has requested me to investigate the distribution of the gall-ducts in the various game animals coming under our observation and thus to supplement an interesting study in comparative anatomy, started by Dr. Mentzner of Rochester. I have agreed to work out the diagram of the gall-bladder and ducts on part of the ninety-six species that inhabit this part of Africa.

Our prime object is to hunt with the bow and arrow the many small game, water bucks, antelope, and other herbivora of the Tropics. We are not attempting to make any foolhardy assaults on lions, elephants, rhinos, and buffalo. The probabilities are that an arrow will kill all of these fearsome beasts, and, under favorable conditions, we may try the experiment. But here (it is only part of sanity) we shall be backed up with "life insurance," the big cordite guns, and it must be remembered that we go in company of two of the greatest African hunters of the age, Simson and White. The latter is considered by Roosevelt the best shot that ever entered the country.

Natives, of course, do kill lion with spears, and the in-

cidence of homicide is fairly small. Still, we are not looking for that form of excitement.

In our equipment, besides a complete medical and first-aid kit, we take four or five bows apiece with 300 arrows. Materials for making 3000 arrows we carry, to be assembled later, with assistance from the natives. Tropical clothing and camp luggage complete the outfit.

Our hunting will take place on the elevated plateau of Tanganyika, where the nights are very cold and the days about as hot as the San Joaquin Valley in midsummer.

So, if it will amuse you, from time to time I shall send a letter spinning across the globe, carried first by a naked, sweating African, running with a spear in one hand and the mail in the other; then by dusty, creaking ox-cart and funny jerk-water Uganda railroad; then ships surging through the mighty deep, transcontinental rail and air-mail to you in San Francisco, telling you how we fare in the far-off land, what strange sights we see, and what adventure we meet.

Yours, as ever,
SAXTON POPE.

ECONOMIC CASE REPORTS

Case 1—One of the organizations located in an Eastern city and practicing medicine illegally in California is energetically "sampling" and "circularizing" our people with propaganda about curing rupture by local application.

As a work of art, read this from their claims:

"The free sample treatment is, of course, not sufficient in quantity to be of any permanent benefit. It is sent so you may know what — is like and how easy it is to use. But if it is possible for this small quantity to organize a normal process of repair, you will understand just how so many thousands have been able to report lasting freedom from rupture after using the full self-treatment supply in connection with my perfect holding Comfort Support."

The submission of this class of stuff to doctors by their patients is a wholesome sign of increasing intelligence of the public.

Case 2—Another Chicago concern is telling our people how they can have their lives extended ten years—for a fee. They claim that:

"Our work is not a fad of an hour. It is not a course in physical culture; or dietary, or drugless healing. We make a thorough examination of the urine, tell you what we find and explain the significance, and keep a copy of all reports so that the subscriber gets with each report a statement of the present condition and a comparison with the previous reports."

Many Californians are sending their good money and their "canned urine" to concerns of this class, and are trusting these "health by mail" "doctors" to guide them in preserving their most precious asset—HEALTH.

Case 3—And They "Fall for It"—The following is reading matter in a widely read women's magazine which conducts a health club headed by a doctor of medicine:

"This doctor (not the editor of the medical department, but another one) has never had a failure. He discovered his process for removing hair in treating a skin disease on a man who wore a beard. He invented a machine which perfected the process, and for twelve years his twenty-four machines have been in constant use. There is absolutely no return of the growth, and women in a highly nervous condition have found the treatment beneficial to their general health. *We should be glad to send you privately any information you wish in regard to this matter.* We feel how great is this man's gift to women, freedom from sensitiveness and self-consciousness. As we have said before, we think that self-consciousness, and not money, is the root of all evil."

If you can beat that—outside of radio health land—we would like to hear from you.

In this world if you do not say a thing in an irritating way you may just as well not say it at all, because people will not trouble themselves about anything that does not trouble them.—Bernard Shaw.

Medicine Before the Bench

Findings and Comments of the Courts on Acts and Omissions of Doctors

(EDITOR'S NOTE—*The law reports contain many interesting decisions, involving the reputations and fortunes of doctors. In this column in each issue a brief summary of one or more decisions and comments of the several courts of last resort upon the cases will appear. The matter will be selected by our general counsel, Hartley F. Peart, who, with Hubert T. Morrow, attorney for Southern California, will contribute from time to time.*)

In a case where a physician was charged with having negligently failed to remove a sponge from his patient after the performance of an operation for appendicitis, the interesting question was presented as to whether or not the statute of limitations commenced to run from the time the sponge was negligently sewed up in the plaintiff's abdomen, or from the time that the physician ceased to treat the plaintiff and the relationship of physician and patient had terminated. It appeared that the operation was performed on November 1. The physician neglected to remove a sponge which had been used in the operation, but thereafter continued to treat the plaintiff until March of the following year. The statute required actions of this character to be brought within one year. The defendant's counsel contended that when the sponge was negligently left in the patient the statute commenced to run, and the subsequent failure to remove it did not arrest the statute or give rise to a new or independent cause of action. The Supreme Court of the state where the cause was pending refused to follow this reasoning, and followed a previous decision involving the liability of a veterinary surgeon, holding that it was the defendant's duty to give to the case such continued further attention, after the operation, as the necessity of the case required. The court says:

"This, we believe, is a sound and salutary rule to govern the relation existing between the patient and the surgeon, who practices his profession and undertakes the serious operation described in this record. If such care is due to a dumb animal, it is surely due to a human being. . . . If we call malpractice a tort in this case, it is a tort growing out of a breach of contract which the law implies from the surgeon's employment and undertaking to perform the operation. We have seen that it was a continuous obligation and recognized by the law, and it was alive and binding so long as the relation of physician and patient subsisted. If so, it was the ever-present duty of the surgeon to remove the sponge from the body of the patient. It was a constant and daily obligation to use ordinary skill and care, and if by omission or negligence he had left a foreign substance within the walls of the incision at the operation, it behooved him to afford timely relief. Neglect of this duty imposed by a continuous obligation was a continuous and daily breach of the same, and, as the facts show, caused continuous, increasing, daily and uninterrupted injury. Should she (the patient) have brought her action immediately following the sewing up the walls enclosing the sponge? If she had done so, there were as yet no injurious consequences and but nominal, if any damages, could have been recovered. The injury consisted not so much in leaving the sponge within the cavity, as negligently continuing it there, or allowing it to remain there from day to day for about a year and until he dismissed her from his attentions. The grievance of the plaintiff was not alone confined to the negligence in the operation, but also in the painful consequences which followed, and which, as he repeatedly assured her, would soon disappear, if she would but patiently wait. . . . The facts in the case at bar show a continuous obligation upon the plaintiff in error, so long as the relation or employment continued, and each day's failure to remove the sponge was a fresh breach of the contract implied by the law. The removal of the sponge

was a part of the operation, and in this respect the surgeon left the operation uncompleted."

It was held that the action was not outlawed, if brought within one year after the defendant ceased to treat the plaintiff.

Decoys not Permitted to Ensnare Innocent into Committing a Crime—The legal privileges of decoys for ensnarement was an important point in the recent trial of a doctor for violation of the Harrison Anti-Narcotic law. The legal status of "ensnarement" was presented by the court in the following language:

"The court instructs the jury that, while it is permissible for government agents and officials, through detectives and decoys, to entrap criminals, or to present opportunity to those having intent to or who are willing to commit crime, it is not proper for government officials, agents or decoys to incite to or create crime, for the purpose of prosecuting it or punishing it, and if the jury believe from the evidence that the government's agent and witness, John Walter McDonald, through false statements made to the defendant to the effect that he was suffering from a disorder of the stomach and required morphin for the purpose of relieving the pain incident thereto, or that he was an addict or had been an addict, and found it necessary to occasionally take small doses in an attempt to cure himself from the drug habit, and through such statements, which were false, procured from the defendant the morphin for the dispensing of which the defendant stands indicted, and the defendant, believing the statements made by McDonald were true, was induced thus to violate the law, and that said defendant was not theretofore willing thus to violate the law, and would not otherwise have violated the law, then the jury should find the defendant not guilty."—Journal A. M. A.

California Association of Physiotherapists (reported by Florence C. Burrell)—Uses of the head-sling in physiotherapy and treatment of flat-foot were the subjects at the monthly meeting of the San Francisco branch of the Association of Physiotherapists at the Ethel Moore Health Center, Oakland.

H. W. Hitchcock, M. D., gave five types of disabilities that could be relieved by head traction given with hot packs over the spastic muscles during suspension. First, the relaxed child with loose ligaments who often gets a kink in the neck, with accompanying muscle spasm. Second, the carnivorous, often neurasthenic, type with poor posture and pain in the back. Third, those with sudden low-back strain, with negative x-ray findings, who may be relieved by strapping during suspension. Fourth, those with hypertrophic changes in the spine who have headache and pain. Fifth, used in applying plastic collars, etc. Relief of muscle spasm is the object of the treatment.

W. F. Holcomb, M. D., spoke on the various stages of static foot deformity and their treatment. He brought out the fact that most of the common disabilities of the foot are due to improper uses of the foot, with especial regard to the attitude of the feet during locomotion. The progressive stages of the deformity were (1) abduction of the forefoot with its consequent ligamentous and muscular strain, (2) lowering of the longitudinal arch with its consequent loss of elasticity, and (3) rigidity of the foot in the deformed attitude. Correction of the first stage is entirely possible by the common supportive means along with instruction, exercises, and proper shoes. Plates were discussed with regard to treatment of the second stage. It was brought out that the Whitman plate was rather a corrective brace than a support, while the Boston foot plate was a support without any idea as to the correction of the existing deformity. Shortening of the tendo-achilles was to be looked for in every case of flat-foot, for without treatment of this condition relief was not always afforded. For rigid flat-foot and congenital flat-foot (pes planus) open operation or manipulation under anesthesia was deemed necessary.

Patriotism cries, "God give us men," but the parties say, "Give us votes and offices," and Congress proceeds to create a commission. Thus responsibilities are shirked and places are multiplied.—Henry Waterson (recent biography).

Physicians' Sterilizers

Every Doctor's office should be equipped with proper sterilizers.

Illustrations show two of the many styles we carry for Sterilizing water and instruments. All our sterilizers can be heated by gas or electric current.

California's Leading Surgical Supply House

PARATHYROID

Powder and Tablets 1-20, 1-10 Grain

—And—

Parathyroid and Calcium Tablets

1-20 Grain Parathyroid

2½ Grain Calcium Lactate

Parathyroid preparations are indicated in Paralysis Agitans, Tetany, Indolent Ulcers and lesions that refuse to heal.

These parathyroid products are carefully made from fresh normal glands of young cattle.

Pituitary Liquid, standardized, in ampoules, surgical 1 c. c., obstetrical ½ c. c. Premier preparation of Posterior Pituitary.

Anterior Pituitary powder, 2 and 5 grain tablets. Pituitary whole gland, powder 1 and 2 grain tablets. Posterior Pituitary, powder and 1-10 grain tablets.

MEDICAL STRAWS

By THE EDITOR

Experience is fallacious and judgment difficult

Henry V Said of the Doctor—"In peace he works in stillness for the saving of the human life, but in war his fierceness to save in the midst of destruction has no parallel."

It Depends Upon Whose Ox—"They tell us that when Henry Ford established fixed fees and put the physicians of his hospital on a salary, the plan worked well until his grandchild had mastoiditis. A hurried call was then sent to Detroit for men whose fees are fixed by themselves."

IT SEEMS to me that a great tendency exists (among physicians) to work for a selfish progress, that we are not sufficiently interested at heart in the collective advancement of our profession, that a spirit of rivalry is too manifest, that co-operation exists only in small cliques, that seldom do we apply the Golden Rule in regard to our fellow-practitioner.—H. M. Higgins (Journal of the Arkansas Medical Society).

CHARITY is contemptibly easy both to give and receive, but helpfulness costs even to receive.—Henry Ford.

IT IS significant that most of the men that come here have no trade and have never learned to work steadily.—Warden Johnston (to Commonwealth Club on a visit to San Quentin Prison).

Send them to "Habit Clinics" if you must, but, for the sake of civilization, be careful about rejuvenation."

DR. EUGENE KELLEY, STATE COMMISSIONER OF HEALTH OF MASSACHUSETTS, SAYS THAT WE MUST TAKE THE LETTER "R" OUT OF FREE AND PLACE THE HYGIENIC WORK ON A FEE BASIS.

THE fundamentals of preventive medicine as applied to the individual are entirely different from those of public health activities, as they are from those of curative medicine.—J. Pentado Bill (Boston Med. and Surg. Jour.).

COMMERCIALIZED health examinations are bad for patient and doctor. Periodic physical examinations will be commercialized by institutions and capitalized by the quacks, unless the medical profession meets the growing demands.—Long Island Medical Journal.

Is This So?—"Formerly," says the New York Board of Health, "the health of the baby was a local problem and emphasis was placed on family care. Today the complex character of living conditions causes it to assume a much broader aspect, and community control cannot be avoided."

Is removing the responsibility of the child's health from the parents and family physician to "community control" likely to benefit the baby? Poor babies.

TIME flies nowadays, and doubtless a man could pick up a genuine antique Mah Jongg set if he looked around.—Detroit News.

SOME folks haven't sense enough to know that some things can't be done, so they go ahead and do them."

IT BEHOOVES the medical profession to offset and hold back a rising tide of popular demand and sentiment for free examinations and advice.—Henry L. K. Shaw (Nation's Health).

THERE are enough people in the world now, too many, who believe they have done something when they have only made a speech about it or written another law on the statute books.—Angelo Patri (Liberty).

PERHAPS the most revolutionary conception in medicine is that serious diseases, functional disorders, and organic inferiority of diverse types, may be caused by a deficiency or excess, or a combination of deficiencies and excesses, of certain food constituents.—N. Philip Norman (Journal of the Medical Society of New Jersey).

What About Tomorrow?—*The welfare federation of today* is to all intents and purposes the *cabinet of the unofficial government of the city*, supplementing the official government with quick resource, with experiment, demonstration and unselfish non-political public work.—Haven Emerson (The Survey).

EVOLUTION is defined by Henry Fairfield Osborn (Forum) as "a continuous creation of life fitted to a continuously changing world. The process consists of new forms and combinations of energy in the animal world, of new means of enjoying the rest of the universe both in the animal and in the human world, of new moral, spiritual, and intellectual powers gained sometimes slowly, sometimes suddenly."

Attention, W. J. B.!

IN MASSACHUSETTS any physician who associates himself with an unregistered person for the purpose of carrying on the practice of medicine is open to prosecution and may be fined or suffer loss of his registration.—Boston Med. Surg. Jour.

YOU may, if your arithmetic is erratic, add up a column of figures a dozen times and get different sums. Only one is correct. It is necessarily the same about the more complicated problems of life, only we cannot see it so clearly.—Edwin S. Slosson (Scientific Monthly).

UNLESS a man knows something about the patient who has the disease, it is not going to benefit him to know everything about the disease.—Illinois Medical Journal.

THE annals of mankind show that disciplined men have built powerful nations that undisciplined men have allowed to perish from the earth. In these times thoughtful people are wondering whence will come the disciplined men of the next generation. From the average American home, discipline has all but disappeared along with the old-fashioned fireside.—Thomas H. Russell (Red Book).

What About This?—One of our state governors, in replying to requests that he appoint a physician to an important post in one of the state health organizations, said, according to Boston Med. and Surg. Jour., that "physicians nowadays were so narrowly trained in their various specialties that he did not know where to turn to secure the services of one who could take a broad view of any public matter."

THE most serious indictment of medical practice today is that it is superficial. Unless guidance of the public in this direction is to be left to sociologists, and among these, enthusiasts, faddists and blundering well-meaners, the medical profession must be not only better educated, but *differently* educated.—Henry B. Favill, M.D.

Boiling instruments still the safest sterilization

LONG proven sterilizing technique demands that instruments be boiled in water for ten minutes, and that they be removed immediately without contamination.

Touching the hands to *unsterile* tray handles may transmit infection. This is not possible with a CASTLE because the handles are as sterile as the instruments.

CASTLE sterilizers follow only the long proven technique of bacteriological authorities. They do not employ new and untried methods. Refinement of detail, however, makes them the safest and the most convenient to use.

*Dry heat is an uncertain agent
and may injure instruments*

BOOK REVIEWS

This column is conducted solely in the interests of California and Western Medicine readers. Critical comment, favorable and unfavorable, purely from the standpoint of the interests of the medical reader, will be made about books selected from the larger number acknowledged in the Books Received column. The advertising columns are open to book publishers who wish to make additional statements about their publications.

Manual of Psychiatry. For the medical student and general practitioner. By Paul E. Bowers. 365 pages. Philadelphia and London: W. B. Saunders Company. 1924.

Definitions have long been out of fashion, but here we see a revival, there being one for every type of mental disease with one for insanity to start off with. The book has the appearance of being got up for students who were cramming for an examination, and it would serve excellently for that purpose, but it would never entice an indifferent reader to explore the mysteries of psychiatry. There are no fresh viewpoints, none of those pleasant surprises that one comes upon in the inspired book. There open up no new vistas that beckon one on to distant enchantments. The cause of psychiatry is not to be advanced by such means. The adding of such a manual to the already groaning shelves is uncalled for at a time when even the publishers are beginning to cry out for "fewer books and better ones."

The one chapter which rises above mediocrity is that on the relationship of insanity to crime. E. W. T.

Pediatrics. By Various Authors. Edited by Isaac Abt. Vol. III, 1051 pp. Philadelphia and London: W. B. Saunders Co. 1924.

This third volume of Dr. Abt's reference work on pediatrics upholds the standard of subject matter and editorial excellence attained by the preceding ones. When one considers the enormous difficulties under which this large piece of work was accomplished, credit can not be too generously given not only to the contributors, but especially to Dr. Abt.

As a reference work the book is extremely valuable

Hunting With the Bow & Arrow

BY DR. SAXTON POPE

An attractive volume containing 256 pages and 50 illustrations, printed on art paper, substantially bound in buckram with stiff board covers and crash russet sides appropriate to outdoors. There are sixteen chapters, each dealing with some phase of archery. They describe the Indian methods of using the bow; how to make bows and arrows; the ballistics of archery; how to shoot; hunting small game — the coon, fox, coyote — and relate experiences in killing deer, mountain lion and bear with bow and arrow. The illustrations are from photographs taken in the field and give the reader a clear picture of the hunting scenes. It is a book that every archer and sportsman should have in his library and should be read by all who love this fair sport and adventure.

True Economy

Genuine economy consists of buying only those articles which will give the greatest service for the greatest length of time.

The PELTON Lincoln Model Sterilizing Unit, built entirely without solder for complete sterilization by dry heat as well as boiling, is truly economical.

But there's another equally important reason for its soundness as an investment:

A large initial outlay is unnecessary. The Cabinet may be purchased separately or with a single Sterilizer, and further Sterilizers added as you need them. The Lincoln Model Unit enlarges with your practice.

Illustrated is the Lincoln Model Cabinet to which have been added instrument, dressing and water Sterilizers, making the No. 1516 Unit. This Unit is priced at \$210 complete.

BOOK REVIEWS

(Continued from Page 349)

and is exceedingly well indexed, which is such an essential attribute.

I should like particularly to recommend the most excellent chapter on orthodontia by DeVries. This subject is of vast importance to pediatricians and should be so recognized. The great advances made in recent years in this field have very definitely favored the progress made in correcting the nutritional disturbances of children.

Hayes has an intelligent and reasonable discussion of the function of the tonsil and the present status of treatment of its pathology.

Dr. Abt's chapter on the nutritional disturbances of infancy is a particularly lucid and entirely up-to-date exposition of the modern ideas of these derangements and of their therapy.

The internist in children's diseases will find the whole subject of surgery of the gastro-intestinal tract excellently presented.

The physiology of respiration and Byfield's chapter on chronic infections of the upper respiratory tract are well worth reading.

C. F. G.

Normal Bones and Joints Roentgenologically Considered. Annals of Roentgenology, Vol. 4. By Isidore Cohn. 219 pp. Illustrated. New York: Paul Hoeber. 1924. Price, \$10.

One of Hoeber's beautifully printed atlases. It illustrates the various stages of ossification of the shoulder, elbow, wrist, hip, knee, and ankle. It is an invaluable book of reference for radiologists, surgeons, orthopedists—for anyone who is called upon to study roentgenograms of children's and young people's bones and joints. L. E.

A Treatise on Orthopedic Surgery. By Roual Whitman. 7th ed. 991 pp. Illustrated. Philadelphia and New York: Lea & Febiger. 1923. Price, \$10.

A new edition of a valued text. Some of Whitman's femoral conditions are more fully treated—his treatment for fractured femoral necks, his astragalectomy, for instance. His own ideas, at times differing from those of many other orthopedic surgeons, are brought forward. This is no defect, but an advantage in a textbook. A chapter on military ratings will also be of interest to industrial surgeons. L. E.

Essentials of Prescription Writing. By Cary Eggleston. 3rd ed. 146 pp. Philadelphia and London: W. B. Saunders Company. 1924.

A not unuseful little manual. Almost a quarter of its

BOOK REVIEWS

(Continued from Page 352)

pages is taken up by a grammar and vocabulary of dreadful dog Latin, remnant of the late Middle Ages, kept alive by doctors and licorice-scented pharmacists' clerks in their prescriptions. It is a good thing that the art of medicine has not yet lost all of its alluring flavors of magic or mysticism. L. E.

Students' Guide to Operative Surgery. By Alfred T. Bazin. 126 pp. Montreal: Renouf Publishing Company.

A classroom guide for students at McGill University, to whom its usefulness will be confined. It cannot compare with von Bergmann's or other standard guides. L. E.

Safeguarding Children's Nerves. A handbook of mental hygiene. By James J. Walsh and John A. Foote. 272 pp. Philadelphia and London: J. B. Lippincott Company. 1924.

Dr. Walsh is a scholar who touches little that he does not adorn, and this book is an example of it. His scholarship sticks out from beginning to end of this little volume. The wholesomeness of viewpoint is very noticeable throughout, and there is none of the mawkish sentimentalism which so often offends in books on kindred subjects. There is a welcome freedom from faddishness, and while words are not minced and there is frank facing of ugly things, the morbid insistence upon sex that pervades much of the stuff of the past decade, is missing.

It is an excellent guide for anyone who has at heart the mental welfare of the child. E. W. T.

Modern Methods in the Diagnosis and Treatment of Renal Disease. By Hugh MacLean. 2nd ed. 110 pp. Illustrated. Philadelphia and New York: Lea & Febiger. 1924.

This is not a compilation of methods used in the diagnosis and treatment of renal disease. Only three pages are given to surgical diseases of the kidney. It is really a very brief review of certain simple methods which the general practitioner may use in the diagnosis of Bright's disease, and even in this narrow field little is said, and

If its for the physician, hospital or sickroom, we have it

Large clinical experience conducted by clinicians of note has established the superior efficiency of ALQUA in overcoming the disagreeable and dangerous symptoms of Acidosis in—

ALQUA WATER contains the alkaline salts found normally in the human body. Physicians will find it invaluable where alkaline treatment is indicated. Not only is it very effective in the treatment of most acute and chronic diseases caused or accompanied by acidosis, but it is an ideal preventive, in that it neutralizes destructive acid by-products in the system.

GLACIER SPRING WATER with which Alqua is prepared, originates in the upper glaciers of Mt. Shasta, California, U. S. A., (Elevation 14,442 ft.) Its great purity without artificial treatment, renders it especially suitable for affinitization with the added salts, thus forming a combination that is remarkable as an alkaline water. Glacier water is released from the earth at Shasta Springs where it is put into block-tin lined carriers and transported to the Company's laboratory where the alkaline salts are scientifically added under the directions of an expert chemist, thereby creating, through the united efforts of science and nature, the wonderful medicinal virtues of Alqua Water.

ASK YOUR PHYSICIAN ABOUT IT.

Constipation

One of the many advantages that may properly be claimed for Mellin's Food as a milk modifier is particularly emphasized by bowel movements normal in consistency and regularity.

Babies whose diet is prepared with a sufficient amount of Mellin's Food to thoroughly modify the quantity of milk necessary for the daily nutritive requirement receive food capable of normal digestion and assimilation and are therefore not troubled with constipation or disturbances caused by faulty elimination of waste matter.

Literature based upon evidence of many years' accumulation is ready for physicians who are interested. In making requisition, please ask for "Constipation" pamphlet.

Are There Those Above the Law—In a case in which the practice of Christian Science was held to be, as a matter of law, "the practice of medicine," the Supreme Court of Ohio said:

"That the practice of medicine may be regulated by legislation, has been decided in every court in which the question has arisen." (State v. Marble, 72 Ohio St. 21).

The Supreme Court of California, in 1904, said:

"In fact it must be conceded that it is a common and valid exercise of legislative power to prescribe regulations under which only those persons possessing proper qualifications shall be admitted to the practice of any profession or calling requiring special skill. This right of legislation is always recognized as a salutary and wise exercise of the police power of the state for the protection and safety of the public against unskillful and incompetent persons."—Harry Eugene Kelly (Federation Bulletin).

ACIDOSIS

By some investigators ACIDOSIS has been designated as a diminution of the alkalinity in the blood; by some as an excess of acid in the blood; by others as a lessening of reserve supply of fixed bases in the blood.

If the acid combining power of the blood is impaired BY A LACK of the alkalies, sodium bicarbonate and sodium phosphate, and may be built up by the process of food ingestion, *may we ask* attention to CALSO WATER, which is rich in the potential alkalies.

BOOK REVIEWS

(Continued from Page 354)

that little with no assurance. The rough clinical estimation of the concentration of urea in the blood and urine is recommended. The only other test described in detail is the determination of diastase in the urine, but elsewhere the author admits that he has little confidence in the results. There are a few pages on the histology of Bright's disease, but there is no attempt to relate clinical and pathological observations. The somewhat archaic division into parenchymatous and interstitial nephritis is retained for clinical diagnosis. There are some very sensible remarks on the possible fallacy of conclusions based on blood urea determinations. There are some first-hand observations on the incidence of albuminuria and casts in apparently normal individuals. Aside from these two instances, the chief virtue of the book is its attitude of half-suppressed skepticism and its chief fault that the underlying doubt is not allowed to come to full fruition. T. A.

Medical Gynecology. By Samuel Wyllis Bandler. 4th Ed. 490 pp. Illustrated. Philadelphia and London: W. B. Saunders Co. 1924.

The fourth edition of Bandler's Gynecology has appeared. It does not profess to be anything but a medical gynecology and, therefore, has a limited scope. Valuable chapters have been added by Dannreuther, Mannheimer, and Highman which are instructive, although Dannreuther's statement in regard to Heitzmann's criteria in the diagnosis of the site of origin of epithelial cells seen in urine will not find general acceptance. The chapter containing the use of electricity should have been revised and brought up to date. As it stands, it creates the feeling that galvanism is a sure cure for every ailment of the generative organs, while we know only too well that its use is confined almost exclusively to the trophic disturbances of the uterus. This chapter also lacks an intelligent explanation why electricity is of some use in the treatment of women.

The chapter on the endocrine glands is fanciful and often hazy in its deductions. It could stand material condensation and is in need of a thorough house-cleaning. It is unnecessary to point out that up to date gynecology should not advise atmocausis, while it should contain the recent advances in diathermy, the dangers of x-ray treatment of functional disorders of young women, a more

ALUM ROCK SANATORIUM

FOR THE TREATMENT OF TUBERCULOSIS IN ALL ITS FORMS

The Sanatorium adjoins Alum Rock in the eastern foothills of San Jose, 900 feet above sea level, and overlooks the entire Santa Clara Valley. The climate is ideal throughout the year. The distance from San Francisco by rail or motor is fifty miles. The buildings are situated in the center of a beautiful ten-acre tract under cultivation. A hedge of eucalyptus partly surrounds the place and there is a great variety of flowering shrubs, citrus and pine trees. The aim of the Staff is to give tuberculous patients intensive individual treatment and each case will be carefully studied with this end in view.

CALCREOSE

R. RAMSDEN WADE reports (Brit. M. J. 1: 158, Jan. 24, 1925) having had good results from the administration of creosote in the treatment of cases of influenzal pneumonia and chronic influenza which are very liable to be mistaken for phthisis.

POWDER—TABLETS SOLUTION

CALCREOSE (calcium creosotate) is a mixture containing in loose chemical combination approximately equal weights of creosote and lime. It has the pharmacologic activity of creosote, but apparently does not have any untoward effect on the stomach.

Samples of Tablets on Request

THE MALTBIÉ CHEMICAL COMPANY - NEWARK, NEW JERSEY

BOOK REVIEWS

(Continued from Page 362)

thorough discussion of the patency tests of the Fallopian tubes and disturbances of the urethra. I noticed that the cystoscopes spoken of are still of the type where the window points upward. In the treatment of gonorrhea, I miss a thorough discussion of dye treatments.

Aside from this, the book contains many helpful hints for the medical treatment of the generative disturbances of women. But since, on the other hand, it is impossible to separate medical from surgical gynecology, it is questionable if the book will give full satisfaction to anybody but a student or a beginner in the practice of medicine.

L. A. E.

Pellagra Information—Doctors Goldberger and Tanner (Public Health Reports) conclude their interesting inquiries into the cause and prevention of pellagra in these words: "A liberal supply of protein, presumably of good biological quality, does not completely prevent, though it may modify, the clinical picture of pellagra by notably delaying or preventing the development of the distinctive dermatitis. This modifying action may be of an indirect, sparing nature. In the prevention (and presumably causation) of pellagra, there is concerned a heretofore unrecognized or unappreciated dietary factor which we designate as factor P-P. This may be effective with but little, possibly without any, co-operation from the protein factor. Factor P-P may possibly play the sole essential role in the prevention (and causation) of pellagra. Factor P-P is present in brewers' yeast, in milk (on the basis of our experience with fresh meat) in lean beef; it is very low or lacking in dry soy beans, dry cowpeas, butter, cod-liver oil, and canned tomatoes."

Good and efficient public service makes it mandatory that responsibility be fixed definitely. Then only can a public official be held to a strict accountability. Responsibility can be definitely placed only if it be reposed in an individual.—Frank O. Lowden.

Howard Stout, and Hudson
Vaughan, Atlantic City.

Speed, Convenience, Economy *in the laundry of a famous resort hospital*

Since the installation of a completely equipped "American" laundry in the Atlantic City Hospital, the authorities of this famous resort hospital have been impressed with three distinct advantages the laundry offers. They find it possible to have the bed linens, nurses' uniforms, towels and other articles laundered daily—with surprising speed; they are able to economize in their stock of linens because of this rapid service and they also find it most convenient to have such highly important work as the hospital washing directly under the supervision of their own officials.

The Atlantic City Hospital is only one of the many hospitals and institutions that are taking advantage of the benefits provided by a laundry operated as a regular part of the hospital service. Like most of these laundries, the entire plant was designed and installed by "American" engineers, and "American" equipment was used throughout.

The American Laundry Machinery Company maintains a corps of laundry specialists who will be glad to advise you concerning your laundry problems without obligating you in any way. A card will bring full details.

CHLORINE GAS

IN WHOOPING COUGH

AMPOULES OF CHLORINE GAS "Roehling" offer the most convenient and practical method of using chlorine gas in cases of whooping cough.

No apparatus to bother with, no special preparation. Simply pour the contents of the ampoule into a dish in a closed room. Children can be treated without realizing they are under treatment.

Ampoules of Chlorine Gas are equally convenient in treating all of the respiratory conditions in which chlorine gas is indicated. They are sold by most of the reliable physician supply houses. The price is \$4 a dozen. West of the Rockies \$4.25. In less than dozen lots 50 cents an ampoule is customarily charged. Sold to physicians or on physician's prescription only.

WILL ROSS, INC.

457-459 E. WATER STREET
MILWAUKEE, WIS.

DISTRIBUTORS

Make your own Carrel-Dakin Solution with the ampoule—one AMPOULE OF CHLORINE GAS "Roehling" added to 175 c. c. pure water and 3.75 grams sodium carbonate (monohydrate) makes six ounces of fresh, standard Carrel-Dakin solution. For your convenience we are packing sealed envelopes containing 3.75 grams sodium carbonate (monohydrate). Your dealer can supply.

FOR THE PATIENT WHO BALKS AT BRAN

ZED

The same patient who registers a decided dislike for bran gladly takes to ZED. For ZED is a delicious laxative biscuit in which the coarseness of the bran is hidden by the fine flavor of whole wheat.

In addition, milk, natural fruit and vegetable extracts are used in the blending of ZED to make it tasteful and appealing—and also to supply important mineral elements.

Thus the patient with a marked antipathy to bran finds himself with a marked liking for ZED. There is nothing in ZED to remind him of that "straw-like" taste he has mentally associated with bran. There is everything in ZED to make him like to eat the amount you advise.

We will be glad to supply to any physician on request a full-sized package of ZED for trial purposes.

LOMITA VISTA

Convalescent and Rest Cottages

Address: MISS MAUD S. MACINTYRE. Telephone, Los Gatos 237

This delightful home-place is ideal for those who like to slip away from the hurry and hum of things to enjoy a time of rest. Here you follow the dictates of your tastes and preferences. You lie abed in the morning and have breakfast served in your room—or you are up with the sun to enjoy the hush of early morning when the spirit of rest pervades *Lomita Vista*. If you like to read and study, you will enjoy the charming, secluded places that you will find here.

We will gladly give as references the names of prominent physicians and others.

THE HYDROPATHIC DEPARTMENT is especially built for, and devoted to, the treatment of general diseases excluding, however, surgical and infectious diseases. Special attention is given to the treatment of nervous diseases of the functional and organic type. Our laboratory is equipped for the study of secretions and excretions. A modern X-ray department is also available.

THE COTTAGE DEPARTMENT (For Mental Patients). This department is some distance away from the Hydropathic Department and has its own facilities for Hydropathic and other treatment. It consists of a number of cottages, some of

them for individual patients, offering the very utmost in privacy and comfort. The cottage system permits homelike surroundings and segregation of patients in accordance with conduct.

GENERAL FEATURES

1. Climatic advantages not excelled in the United States.
2. Beauty of the grounds and of the neighboring canyons and mountainous country.
3. Facilities for indoor and outdoor gymnastics under the charge of an athletic director.
4. An excellent occupational department providing occupation and diversion for every variety of nervous and mental patient.
5. Well trained and large medical and nursing staff so that careful individual attention is given to each patient.
6. Rates (inclusive of medical care, hydropathic and massage treatments, also general nursing) \$45.00 per week and upward.

Pollen Asthma

SEASONAL asthma is usually caused by pollen sensitivity. Even in perennial asthma, pollens are frequently found to be primary or secondary causative factors. Hence, it is now recognized that in the diagnosis of asthma, pollen proteins should be used in association with food, epidermal, bacterial and other proteins. Diagnostic pollens are, however, of particular importance when testing cases whose symptoms are accentuated during the pollinating seasons.

X-Ray Laboratory of Dr. A. D. Willmoth, Louisville, Ky. Victor Equipment Throughout

Time and Use Reveal Victor Quality

As months and years pass, the Victor X-Ray machine installed in the physician's office or in the specialized roentgenological laboratory unfailingly responds to the demands made upon it. Day after day, the same trustworthiness in operation, the same certain results as in the beginning.

Thus time and use reveal the quality painstakingly built into every Victor X-Ray machine.

There are simple Victor X-Ray machines which meet the demands of general practice, and powerful diagnostic and deep-therapy apparatus for institutions and laboratories. The same Victor quality is built into all.

We shall be glad to suggest the type of Victor installation best calculated to meet the requirements of the physician in general practice, the hospital or specialized laboratory.

"Properly Develop the Nobler Emotions and All Else Will Follow—Even Efficiency."—"The ideal of 'training for efficiency' in the gainful vocations is crowding out all other ideals, and its dominance means danger. Efficiency in a gainful occupation as an ideal unmodified by higher ideals means selfishness and sordidness. That ideal of efficiency is tending to crowd out all opportunity for fostering the development of altruism and all the finer sentiments that are contributory to it."—Edward Bok (Scribner's).

The pathologist of 1940 will be the greatest correlator of all the facts about disease from the standpoint of the whole patient and not a narrow specialist upon some organ or technical laboratory procedure. Such a well-trained pathologist with a systematic investigative mind can direct any laboratory procedure, evaluate the procedure and correlate the findings with his physical and psychical examinations. Such pathologists will, if I see correctly, be the leading medical consultants in the year 1940. They will know the fundamental differences between investigation, teaching, and application. They will not mix them quite as indiscriminately as they are mixed today, in our efforts to carry on our professional activities.—William C. MacCarty (Jr. Lab. and Clin. Medicine).

Where the "Fear Complex" may Breed Necessary Caution—What is the future of plague? This is hard to predict. More than a quarter of a million cases of plague were reported from all countries last year. With the facility with which rats carry the disease from one country to another on board ship, it seems likely that practically all seaports may sooner or later have to be regarded as actually or potentially infected with plague.—United States Public Health Reports.

Nature has given to men one tongue, but two ears, that we may hear from others twice as much as we speak.—Epictetus.

Analysis of
KLIM
 POWDERED WHOLE MILK

	Dry	Liquid *
BUTTERFAT	28.00%	3.33%
CASEIN	21.28%	2.53%
ALBUMIN	5.46%	.65%
LACTOSE	38.00%	4.53%
ASH	5.76%	.69%
WATER	1.50%	88.27%
CALORIES (per ounce)	149.	18.

* 4½ Ounces to a quart of water

KLIM is completely soluble in water of any temperature

When Used in Infant Feeding

Reliquified KLIM at normal strength has the same analysis and caloric value as natural whole cow's milk and is subject to the same modifications when used in infant feeding

Recognizing the importance of scientific control, all contact with the laity is predicated on the policy that KLIM be used in infant feeding only according to a physician's formula.

KLIM

**is uniform milk
 from which only the water
 has been removed**

K LIM is standardized to 3.33% butterfat content when liquid, or 28% when dried.

When KLIM is reliquified, the butterfat, in fine globular division, remains in a perfect emulsion.

A cream line cannot fail frequently to create differences in the fat content of the baby's bottle or the child's ration. In the latter case the cream too often finds its way to the parent's coffee. KLIM eliminates these hazards.

Your Advertisers Deserve Your Patronage

+

This Journal makes every effort to exclude unworthy advertisements in order to protect its readers. The Journal could be filled with advertisements of the Nostrum class and it would prosper financially; but, since it is published primarily for the benefit of its readers and not for profit, all advertisements, known to be dishonest, or even questionable, are excluded.

Since this policy of discrimination protects you, it should be a privilege to patronize the advertisers in your own Journal. Don't experiment! Buy trustworthy goods from reliable houses.

+

*You may
depend on the advertisements printed in this journal*

Annual Dues

are delinquent March 1. See Constitution and By-Laws, Chapter III, Section 10.

MEMBERS who have not paid their dues before that date will not receive the April number of CALIFORNIA AND WESTERN MEDICINE. Nor will they receive succeeding numbers until such time as they have been reported by their county secretaries as again in good standing.

The April number will contain the program for the Annual Session of the California Medical Association; the May number will be largely devoted to Medical History—particularly California medicine. No member can afford to miss them. PAY YOUR DUES.

In circulation, quality is as much a factor as quantity. Publishers understand that—but not all advertisers do.

The value of advertising space is measured by the results in comparison to the cost. Circulation *quality* counts in determining those results. It is a value that in itself is worth a price.—Standard Rate and Data Service.

Who are the most successful nurses?

Surely, you've remarked the nurse who is confident and poised, capable of meeting any situation.

Isn't she the one who is always in demand?

And haven't you usually noticed that such a nurse is usually smartly groomed? Naturally. Because a smart, distinctive appearance begets confidence, not only in the nurse herself, but also in her associates. Probably that is why so many nurses are turning to PAUL JONES. Paul Jones' costumes are really smart in the true sense of the word. Their trim, graceful lines and modish panels are a triumph of creative skill. Tailor-made, you'd say, to look at them. But they're not—and the lower price would prove it.

Are You Reading **BETTER HEALTH?**

OST newspapers, magazines and publications of every sort are now featuring alleged Health Education, Public Health, and even the practice of medicine by mail, as one of their functions. Of the few magazines that are producing worthwhile informative publicity in this field, **BETTER HEALTH** is the oldest. This magazine is owned and conducted by physicians and devoted entirely to improving the knowledge of the general public on matters pertaining to the promotion, conservation and protection of health; and it is one of the exceedingly small number presenting sound and authoritative health information of the same general type that the physician gives to his patients and friends. A copy should be on the table in your reception room at all times. Every physician, at least in the Western States, should be a subscriber to **BETTER HEALTH** Magazine. It needs your support for many and obvious reasons. If you are not a subscriber, please cut out the coupon and mail it at once. Suggest to your patients that they also subscribe.

To **BETTER HEALTH**, Balboa Building, San Francisco

Please send me **BETTER HEALTH**, the monthly magazine with the Daily Health Service, beginning with the April issue, 1925. Upon receipt of magazine and bill, I will send you \$3, payment in full, for one year's subscription.

SILVER IODIDE IN A NEW ROLE NEO-SILVOL COLLOIDAL SILVER IODIDE

NEO-SILVOL contains 20% of Silver Iodide in colloidal form. It makes an opalescent, milky solution in water, one that leaves a scarcely perceptible stain on drying. These solutions do not irritate the skin or mucous membrane to which they are applied, and their germicidal activity has been fully demonstrated by bacteriological and clinical tests.

The indications for the use of Neo-Silvol include conjunctivitis, gonorrheal ophthalmia, naso-pharyngeal infections with or without sinus or antral complications, cystitis, and acute and chronic urethritis of gonorrheal origin.

One medical author reports one injection (by catheter) of 5 cc of a 10% solution of Neo-Silvol is giving him excellent results in the acute cystitis of young children. He also finds it one of the best remedies he has ever used in the treatment of pyelitis, introduced by way of the ureter.

Neo-Silvol is equal to carbolic acid as a germicide, and twenty times as fatal to the gonococcus.

NEO-SILVOL is supplied in 1-oz. bottles of the granules and in 6-grain capsules, 50 to the bottle. One capsule makes one fluid drachm of a 10% solution.

Write for a sample and literature.

ILETIN (INSULIN, LILLY)

Pure, Stable, Constant in Unitage

As a result of nearly three years research and experience in the manufacture of Iletin (Insulin, Lilly) and in the production of very large lots, we have been able to develop a system of preparation and standardization which insures purity, stability and constant unitage within quite narrow limits.

Iletin (Insulin, Lilly) is free from toxic substances and test lots show no deterioration during a period of more than a year.

Iletin (Insulin, Lilly) is now supplied in containers of two sizes: 5 c.c. vials and 10 c.c. vials. Both the 5 c.c. and 10 c.c. vials bear the same designation: U-10, U-20 and U-40. To distinguish between the two sizes it will be necessary, for example, to order as U-10—5 c.c. vials or U-10—10 c.c. vials. In absence of specifications as to size wanted, the 5 c.c. vials will be supplied.

IMPORTANT ACCESSORIES

Iletin Syringes, Urine Sugar Testing Outfits, Saccharin Tablets, Ampoules Glucose, Benedict's Solution, Plain Agar, Granular. Send for additional information on these items.

All Lilly Products are supplied by the Drug Trade

Petrolagar

(Trade Mark)

A Warning Against Imitations

Imitations flock in the wake of success. It has been brought to our notice that the success of PETROLAGAR has developed some imitators, several packed similar to our product.

None of these imitators has, however, succeeded in producing a product which equals PETROLAGAR in therapeutic action.

The process by which the mineral oil is diffused with the agar-agar in PETROLAGAR was developed after a great deal of research and experiment. It results in the palatable, non-irritating emulsion which gives full lubrication, and which contains 65 per cent of mineral oil. It gives a bland, gelatinous bulk in the intestine. There is no oily taste or after-taste, and the white creamy emulsion has a most attractive flavor.

PETROLAGAR has won its way to a pre-eminent position in its particular field by performance on clinical test.

It has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association for New and Non-official Remedies.

It is prescribed by leading physicians in every section of the country for the treatment of constipation.

It is stocked by the prescription pharmacy.

Complete formula on every package.

Sold in strict conformance with ethical medical procedure, by a house which *does not* advertise any article to the public.

PETROLAGAR is issued as follows:

- PETROLAGAR (Plain);
- PETROLAGAR (with Phenolphthalein);
- PETROLAGAR (Alkaline) and
- PETROLAGAR (Unsweetened, no sugar).

TRUTH ABOUT MEDICINES New and Non-official Remedies

(Abstracts from reports of Council on Pharmacy and Chemistry, A. M. A.)

NOTE—These do not represent all of the actions of the Council, but they do represent those remedies manufactured by firms who co-operate with CALIFORNIA AND WESTERN MEDICINE in its advertising columns, and thereby with the physicians in California.

In addition to the articles enumerated in previous reports, the following have been accepted:

Parke, Davis & Co.—Mercurosal ampoules.

E. R. Squibb & Sons—Squibb's liquid petrolatum with agar.

Antimony Thioglycollamide—The triamide of antimony thioglycollic acid. It contains not less than 30 per cent of antimony. Antimony thioglycollamide and antimony sodium thioglycollate have been tested on rats, rabbits, and dogs inoculated with trypanosomiasis by Rowntree and Abel. These workers suggested the employment of these antimony compounds in the treatment of human trypanosomiasis and the larger animals. Randall has used both of these antimony compounds intravenously and intramuscularly in granuloma inquinae with marked success. In the doses employed they were less toxic than tartar emetic, and the results were more favorable. From the available evidence, the experimental use of these compounds in kala azar would seem to be justifiable. Hynson, Westcott & Dunning, Baltimore.—*Journal A. M. A.*, February 7, 1925, p. 441.

Mercurettes (P. D. & Co.)—Briquettes, each containing finely divided metallic mercury 3.25 gm. (50 grains) incorporated with the obroma (cacao butter) and perfumed. The actions and uses of mercurettes are the same as those of ointment of mercury U. S. P. It is claimed that in the treatment of syphilis and certain forms of parasitic skin diseases where ointment of mercury has been employed, the use of mercurettes permits a more accurate

try
THIOCOL SYRUP "ROCHE"

A valuable remedy, fully described in New and Nonofficial Remedies.

Thiocol Syrup does not disguise the condition by simply alleviating the symptoms but exerts a direct curative effect upon the area of infection.

Does not contain any narcotic or palliative drugs, does not constipate, does not upset digestion. May be safely administered to the youngest children.

Dosage: One-half to four teaspoonfuls,
according to age, three times a day.

*Original bottles contain
6 fluid ounces*

TRUTH ABOUT MEDICINES

(Continued from Page 396)

dosage and is more convenient and less disagreeable. Parke, Davis & Co., Detroit.

Butyn and Epinephrin—As a result of animal experiments recently reported by Hirschfelder, Backer, and Jennison, "the addition of epinephrin to solutions of cocain and saligenin increases their tendency to cause local edema. This is not the case with procain and butyn." According to New and Non-official Remedies, 1924, the use of butyn for injection anesthesia or for special anesthesia does not appear promising, since its toxicity is materially greater than that of cocain. Butyn is a substitute for cocain in surface anesthesia, as for the eye, nose, and throat; it acts through intact mucosa almost as effectively as cocain; solutions of butyn are non-irritant.—Journal A. M. A., February 28, 1925, p. 699.

The Dick Test—The United States Treasury Department has not authorized the interstate sale of any Dick scarlet fever preparation. The Council on Pharmacy and Chemistry does not accept biologic products until they are licensed by the Treasury Department, and, therefore, has not considered the Dick scarlet fever preparation.—Journal A. M. A., February 28, 1925, p. 699.

School Not Enough—The word "school" isn't enough, according to Angelo Patri. It is too limited, too far away from actual things and every-day practices. *The mistake lies in believing that a child's mind is a clean sheet upon which the schools may write whatever they please. Not so. The mind of a child is a book in which are written the life histories of all his ancestors bequeathed to him as his own life story. The book of his intelligence is sealed behind the walls of flesh. It must stay sealed unless the child himself opens it, and the only way he may do that is through his hands. The only way he may add his chapter to the tale is by his hands.*

2000 Miles in Eleven Minutes

As an example of speed in the dispatch of Medical Protective Service we cite you an incident where a Doctor was sued in Los Angeles. Upon receipt of the facts of the case instructions were sent to our Local Counsel in Los Angeles by wire. We were advised by the telegraph office these instructions were in the hands of our attorney in just eleven minutes.

The defendant in a malpractice suit wants service; not theories nor experiments nor a haphazard handling of the facts, but a perfect control of the defense, that can only come from an organization in full possession of all procedure pertinent to every possible situation.

The Worthwhile Things Never Come Easily—A lifetime of struggle and sorrow, hope and fear, must go into our efforts if we are to win the high prize we covet. Nothing comes out of nothing. Once we realize that the loneliness and the pain and the seemingly senseless drudgery of the day-by-day living is the price of growing our souls to where they will yield something fine in love and friendship and work—those greatly to be desired gifts—we will not grudge to pay. We will spend ourselves royally, and life will repay us in riches of content and peace and high happiness.—Angelo Patri.

The More We Learn the More We See to Learn—Medicine has explored disease to a large extent; it is now pioneering into the greater mystery of health. We are only in the far-off dim beginnings of knowledge. Discoveries are yet to be made, greater than those of Columbus—but in another region. The youth of today live in a more thrilling period than those of the merchant adventurers or the early frontiersmen.

Some Data Useful for Self-Analysis—A county medical society has all kinds of physicians in its membership list. There are general practitioners and specialists; insurance men and public health workers; surgeons and laboratory technicians; salaried doctors and fee collectors; young doctors seeking business and retired physicians who cannot drive their old patients away. The membership includes scientists and sports, smokers and haters of nicotine, church-goers and golfers, farmers and society butterflies—every conceivable class is represented except the rascals, and there are so few rascals in the profession that the name of one who happens to afflict a community immediately becomes a byword of scorn among physicians.—Editorial, New York State Journal of Medicine.

The Hartung Hospital Silent Call Signal System

SAFE ————— SILENT ————— SIMPLE

Fully Guaranteed Trouble Proof

Call Station No. 110

The calling station herewith illustrated shows one of the sixteen combinations that we have to offer.

This station consists of the control switch with ball chain, slip connector, pull cord and pear-shaped pendant attached. A slight pull on the cord illuminates a lamp in back of the ruby bull's-eye located in the calling station visible to the patient, a lamp over the door in the corridor, a red pilot lamp in diet kitchen and utility room and the lamp in the annunciator which shows the number of the room calling. These lamps continue to burn until the call is answered and the control switch knob is restored to off position by the nurse.

The push and pull Emergency Switch is used by the nurse only when she finds the patient in critical condition and needs immediate assistance. The nurse, pulling out the button of the Emergency Switch, illuminates a green lamp in the corridor over the door of the room, a green pilot light in the superintendent's office, at the nurses' station and wherever desired. This Emergency call is restored, when answered, by pressing the button of the switch which extinguishes all the green lights. If desired an audible buzzer may be connected to the emergency switch.

*Illustrated booklet and detailed information upon application.

Troy Service and Equipment meets fully the demand for laundry service in the better hospitals.

This letter from Dr. Hedden is conclusive proof that all claims made by us for our service and equipment are fully merited. We can perform the same satisfactory service for your institution, no matter where you are located.

1265 UNION AVENUE

MEMPHIS, TENNESSEE

November 13, 1924.

Troy Laundry Machinery Co.,
East Moline, Illinois.

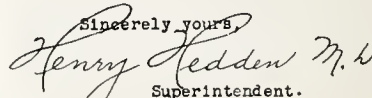

Gentlemen:-

Permit me to thank you for the very excellent service provided by your firm in the installation of our laundry equipment. Exactly three weeks elapsed from date of shipment until our laundry was handling the entire work of the Hospital

The machinery is all of the very best construction, and has given entire satisfaction from the first day. Your construction man, Mr. Heagle, is a very competent workman, and did an excellent installation job in record time. He helped us get our working force organized, and made a number of valuable suggestions to enable us to do high grade laundry work.

Our building was designed and built solely for laundry purposes, and with your equipment, makes the finest institutional laundry in this city, and I doubt very much whether there is a finer laundry of its kind and size in the country

The installation is already occasioning considerable favorable comment from laundry men here, and I think that your company could well point to it as a model selection of equipment and installation.

Sincerely yours,

 Superintendent.

Heart Station

A laboratory for the investigation of Cardiac conditions.

As we are equipped with highly specialized apparatus, in particular an instrument for determining the exact angle in which the patient is being examined, we believe we are enabled to give the heart and especially the Aorta a more than ordinary accurate examination.

An outline of our routine examination is as follows:

- (I) a. History.
b. Complete Physical Examination.
c. Heart Function Tests.
d. Kidney Function Tests.
e. Vital Capacity, etc.
- (II) X-RAY EXAMINATION
a. Pictures in Frontal Position.
b. Pictures at various angles.
- (III) FLUOROSCOPIC EXAMINATION
a. Study of the comparative size and shape of the different Cardiac chambers.
b. Measurement of the Anterior-Posterior size of the heart, frequently the first part to show enlargement.
c. Orthodiagram and Cardiac Pattern—the latter to be used in checking up your own physical findings.
d. An attempt to judge the quality of the heart muscle and determine its probable efficiency and reserve power.
e. Careful measurement of the Ascending and Descending Aorta.
- (IV) ELECTROCARDIOGRAPHIC STUDY
Almost indispensable as a diagnostic aid in many Cardiac conditions.
- (V) METABOLISM TESTS, ETC.
In all cases a detailed and comprehensive report is furnished which will include diagnosis, prognosis and suggestions.
No stay in the hospital is required.
Any single test or examination can be asked for.

Putting Mother's Milk in Baby's Bottle

COW'S MILK contains a much higher percentage of casein than mother's milk because nature intended it for the powerful digestive ability of the calf.

On the other hand, mother's milk contains a lesser percentage of casein and a much higher percentage of lacto-albuminoid—nature's protective colloid which enables the delicate infant organisms to easily digest and assimilate all the nourishment.

When cow's milk is fed to the infant, modification is necessary to make it more nearly correspond to mother's milk.

First among the available colloids is pure, plain gelatine. (Zsigmondy, Z. Anal. Chem. 40, 1901.) When 1% of Knox Sparkling Gelatine, completely dissolved, is added to the prescribed milk formula, the curdling of the casein by the enzyme acids of the gastric juice is prevented, and the nourishment obtainable from the milk is increased by about 23%. It is just like putting mother's milk in the nursing bottle.

Here is the most approved method of modifying baby's milk with gelatine

Soak for ten minutes one level tablespoonful of Knox Sparkling Gelatine in $\frac{1}{2}$ cup of cold milk taken from the baby's formula; cover while soaking; then place the cup in boiling water, stirring until gelatine is fully dissolved; add this dissolved gelatine to the regular formula.

For children and adults follow the same method in the proportion of $\frac{1}{2}$ teaspoonful of gelatine to a glass of milk. Because of its purity, it is essential to specify Knox Sparkling Gelatine.

A package of Knox Sparkling Gelatine, together with the physician's reference book of nutritional diets, will be sent free, upon request, if you will address the Charles B. Knox Gelatine Laboratories, 417 Knox Ave., Johnstown, N. Y.

RADIUM THERAPY

An adequate quantity of radium and complete emanation apparatus affords the facilities essential for modern technique in radium therapy.

DEEP X-RAY THERAPY

Two complete 300,00-volt installations providing every facility for preliminary and post-operative Radiation and X-ray Therapy alone or in combination with other treatment.

X-RAY DIAGNOSTIC LABORATORIES

Completely equipped offer the profession every assistance for roentgenology as an aid in diagnosis.

HOSPITAL AFFILIATIONS

Including a complete high voltage X-ray and Radium Therapy department in the Methodist Hospital amply provide for cases requiring hospitalization.

LABORATORIES

Affiliated for clinical and pathological study and complete facilities for Actinic Ray Therapy.

This institution possesses unexcelled facilities for radium and radium emanation therapy and high voltage X-ray therapy. With modern X-ray diagnostic, clinical and pathological laboratories, complete equipment for electric coagulation, cautery and allied surgery, it offers the medical profession unexcelled facilities for the diagnosis and treatment of neoplastic diseases.

We desire to confer and co-operate with the Medical Profession in the treatment of cancer and other appropriate diseases and request inquiries either in person or by correspondence.

Colfax School for the Tuberculous

Colfax, California

(Altitude 2400 feet)

This institution is for the treatment of medical tuberculosis and of selected cases of extrapulmonary (so-called surgical) tuberculosis.

The Colfax School for the Tuberculous consists of five Hospital Units with beds for patients who come unattended and a Housekeeping Cottage Colony for patients and their families.

The Colfax School for the Tuberculous offers the following advantages:

1. Patients are given individual care by experienced tuberculosis specialists. The patient is treated according to his individual needs.
2. Patients are taught how to secure an arrest of their disease, how to remain well when once the disease is arrested, and how to prevent the spread of the disease.
3. Patients have the advantage of modern laboratory aids to diagnosis and of all modern therapeutic agencies.
4. The climate of Colfax enables the patient to take the cure without discomfort twelve months in the year. We believe climate is secondary to medical supervision and rest, but the fact remains that it is easier to "cure" under good climatic conditions than where these climatic conditions are absent.
5. Colfax is accessible. It is on the main line of the Ogden Route of the Southern Pacific R. R. and has excellent train service. It can be reached by paved highway, being on the Victory Highway, with paved roads all the way to Colfax.

SPECIAL ARTICLE

THE PRESENT STATUS OF ELECTROCARDIOGRAPHY IN THE DIAGNOSIS, PROGNOSIS AND TREATMENT OF HEART DISEASE

By WILLIAM J. KERR, M. D., San Francisco

HISTORICAL.

The normal electrocardiogram.

*Value of electrocardiogram in diagnosis.
Some of the abuses of the method.*

*Recognition of disordered mechanisms of
the heart without the aid of graphic methods
is possible in most instances.*

*Conditions which are shown only by the
electrocardiographic method.*

*Value in prognosis and treatment must
await further study and experimental work.*

*The ultimate goal is to learn what the in-
strument may teach us and then to dispense
with its use for routine work.*

Current was passed through the wire, which was drawn from side to side by the poles of the magnet, while a ray of light from a lamp threw a shadow of a minute portion of the moving wire on a moving strip of photographic paper in the form of an undulating dotted line. Einthoven's invention is an adaptation of this instrument to the study of heart disease, and, as originally constructed, has remained the standard instrument for clinical work.

Einthoven's instrument makes use of a delicate silvered quartz filament or fiber which can scarcely be seen by the unaided eye. It is suspended between the poles of a powerful electro-magnet. Any current passing through the conducting filament, which is placed in a magnetic field at right angles to the magnetic current, causes the filament to oscillate forward and backward according to the ascent or descent of the current. The amount of oscillation depends upon the strength of the magnetic field, the strength of the action current and the resistance in the filament. The movements of the filament, activated by cardiac action, are recorded by projecting its shadow, magnified by a high-power microscope, on a moving photographic plate or film. The time interval is recorded by photographing the shadow of a rotating spoked wheel activated by a tuning fork. The electromagnets are fed by an accumulator battery. The source of light was originally provided by a powerful arc lamp with a water chamber interposed to prevent injury to the filament. Many clinicians today employ an incandescent lamp (Point-O-Lite), which gives a constant beam of brilliant light. The action current originates at the heart and is drawn off by non-polarizable electrodes, placed on convenient and suitable parts of the body. Several types have been devised, but the one described by Cohn, and perhaps the most suitable, consists of a sheet of lead foil 7.5 cm. wide by 22 cm. long and covered by a strip of rubber sheet 9 cm. wide by 30 cm. long. The strips are fastened together near one end by a brass screw which carries the binding post. Warm salt solution is used as the electrolyte. The electrode is applied over gauze soaked in the solution after preparing the skin, to provide satisfactory contact. The current passing through the filament represents, not only the cardiac action currents, but also the difference of potential between the parts of the body to which the electrodes are applied.

In the body there are action currents of other tissues besides the heart muscle which produce variations in the potential. To offset this, a battery current is introduced which neutralizes this so-called skin current. The tension on the filament is adjusted so that each millivolt of current causes an excursion of one centimeter on the plate. This is the Einthoven standard for comparison, which is generally used in clinical work.

Briefly, then, the complete apparatus consists of (1) a string galvanometer, including an achromatic

THE credit for the introduction of the string galvanometer into the field of clinical medicine should be given to Einthoven. Long before his time Matteuci (1843) had discovered that electromotive force emanated from the heart itself. This was confirmed in 1849 by DuBois Reymond by the use of a very delicate galvanometer. Further confirmation came independently by Kölliker and Remak in 1850. Müller and Kölliker showed later (1850-1856) that a special current was developed in the auricles during their contraction. The invention of the capillary electrometer by Lippmann in 1873 led to the construction of the hypersensitive capillary electrometer. Waller, in 1887, suggested that there was a ratio between the contracting force of certain heart muscles and the current that emanates from them. The Ader registration machine or recorder, described in 1887 and used for submarine cable work, consisted of a long vertical wire stretched in a magnetic field.

microscope; (2) a constant source of brilliant light; (3) non-polarizable electrodes; (4) an accumulator battery for the magnetic field; (5) an apparatus for testing the susceptibility of the galvanometer; (6) an apparatus for compensating the "skin current"; (7) a photo-registering apparatus; (8) time-marking apparatus.

Electrodes are usually applied at three points, namely, right and left wrists and left calf. By a combination of these in pairs, we derive the three leads which are related to the action currents in different parts of the heart muscle, and the differences in potential established between the connections at the extremities. Thus:

Right arm and left arm constitute lead I.

Right arm and left leg constitute lead II.

Left arm and left leg constitute lead III.

From these leads the direction, amplitude, and time of the cardiac action currents can be expressed graphically, and a study of these constitute *electrocardiography*.

While the apparatus and its operation appears complicated in description, little difficulty is encountered in acquiring the necessary technical skill for manipulation. Greater skill and study are necessary in interpreting the three curves or leads which constitute the *electrocardiogram*. The *normal electrocardiogram* consists of a series of deflections which are associated with the events of a cardiac cycle, beginning with the origin of the impulse at the sino-auricular node and traversing the auricle, auriculo-ventricular node, ventricular conduction system and ventricular muscle and resulting in contraction. The deflections apparently result from electrical changes accompanying conduction of the impulse and contraction of the muscle. The deflections or waves are grouped according to their occurrence in the cycle; thus P waves are associated with auricular activity and the Q, R, S, and T waves accompany ventricular activity. The electrical changes in the heart precede the actual contraction of the muscle by a brief period. It is not necessary to go into the controversies which were waged about the causation of the different deflections in the normal cardiac cycle. Experimental work is helping to clear up many of the debated points. The final phase, known as the T wave, is the least well-understood deflection of the normal electrocardiogram. The original work of Einthoven (1900-1907), the subsequent studies of Frank and Hess, Eppinger and Rothberger, Kahn, Hoffman, Barker, Kraus and Nicolai, Eyster and Meek, and the brilliant researches of Lewis and his associates, laid the foundations for our present knowledge of the electrocardiogram in health and disease. Since 1910 the literature dealing with electrocardiographic studies has assumed voluminous proportions. A list of the more important contributions is appended. The recent studies have dealt largely with the applications of electrocardiography in diagnosis, prognosis, and treatment.

There can be no question but that the introduction of the electrocardiograph into experimental and clinical medicine has cleared up much of the confusion about the heart. These correlated studies shall serve for all time as one of the most brilliant applications of experimental physiology to clinical

medicine. The cardiac irregularities, one by one, have been studied and described. Heart-block, which was fairly well understood by experimental studies and clinical observations with the polygraph, has been further clarified by electrocardiographic work. This is particularly true of blocking of impulses or defective conduction in the bundle of His, its branches and its arborizations in the ventricles. In the course of extensive studies, the limitations of assistance which we may secure from the electrocardiographic method have been delineated. There are patients who are suffering from obvious cardiac failure who show no deviations from the normal so far as the electrocardiogram is concerned. Patients with extensive valvular disease may show normal electrocardiograms. Some of the more severe cardiac manifestations, such as pulsus alternans, which are demonstrable by the polygraphic or sphygmomanometric methods are shown only rarely on the electrocardiogram. However, in such cases the T waves frequently show abnormalities which have come to be associated with grave cardiac disorders.

VALUE IN DIAGNOSIS

At the outset it should be stated that one who is skilled in electrocardiography and has carefully studied the associated clinical manifestations of disordered action of the heart seldom needs to make use of the electrocardiographic method in diagnosis. This has been made possible by the brilliant observations of Mackenzie and others with the polygraph, and extensive studies by Lewis and numerous physiologists and clinicians with the electrocardiograph. Such a state of affairs does not necessarily condemn the electrocardiographic method as having no place in clinical medicine. Nor does it mean that such an instrument should be restricted to the research laboratories and the medical schools. The ultimate goal in the use of all instruments of precision, as Mackenzie and others have maintained, is to dispense with their use when we have learned all that they may teach us. This stage, however, has not been reached with the electrocardiograph in diagnosis and less so in prognosis and treatment.

Practically all Class A medical schools are today providing some training in the interpretation of electrocardiograms. An increasing amount of instruction is being given in the methods by which disordered mechanisms may be recognized, without instrumental aid. This is highly desirable for those who are entering general practice and may not be able, for many reasons, to carry on their instruction in graphic methods at the bedside. The polygraph, which is portable, may replace the electrocardiograph to some extent, and should be a part of the armamentarium of those doing internal medicine. Some provision must be made for those physicians who have not been instructed in instrumental methods or the interpretation of the findings and the clinical symptoms and signs which they present in the patient. A considerable proportion of patients who are sent for electrocardiographic study present normal variations or simple irregularities which could be readily recognized by the clinician. The patients with such disorders should be spared the expense and the fear that they are suffering from heart disease.

At times the reassurance that may come from the graphic registration and demonstration of a normal or inconsequential finding may be of value in dealing with certain types of patients, but this is seldom necessary for the able clinician.

Experience has repeatedly shown that clinicians should seldom rely on laboratory findings for the diagnosis in any given case. This is also true of the results which may be obtained with the so-called instruments of precision. In rare instances instrumental methods may reveal unsuspected conditions. In general, however, there are symptoms or signs which reveal to the careful observer the true nature of the disorder. Although electrocardiography has helped to place our present knowledge of cardiac disease on a firmer basis, we should not lean too heavily on the results it may show. There are times when we may be misled by normal electrocardiographic findings when the patient is shown to have obvious heart failure. On the other hand, we may err in assigning a grave prognosis in a case where the electrocardiogram shows extensive damage of the heart. It should be remembered that the prognostic significance of certain abnormalities is drawn from average experience, based on statistics subject to wide individual variations.

There are certain normal variations of the electrocardiogram which must be kept in mind. The shape of the curves in the three leads is constant for the individual for long periods of time, barring disease, and may, therefore, be of value in identification. The shape complexes may vary with respiration or changes in position of the heart, produced by displacements, etc. In the case of complete transposition of the viscera, the complexes in Lead I are inverted. None of these call for electrocardiographic confirmation, although they must be borne in mind in interpreting the graphic records.

Inasmuch as the ultimate goal in medicine is to dispense with instrumental aid, when we have learned all that it may be able to teach us, it would be advisable to attempt an exposition of the conditions where such aid is and is not necessary. In the paragraphs which follow, an effort will be made to show the present status of electrocardiography as an asset in clinical medicine. Simple methods of detecting disorders of the heart which require only sight, hearing and touch will be suggested.

The *irregularities* of the heart often confound the physician. The commonest of these is *sinus arrhythmia*, which is of frequent occurrence in children and young adults. Usually the variation in rhythm is associated with respiration, with an increase of rate during inspiration and a slowing during expiration. A deep breath, held, will often cause a marked slowing of the heart. Exercise or anything which speeds up the heart tends to eliminate the irregularity. A study of the jugular pulse in the neck usually shows the three normal waves. This irregularity is of no clinical significance, can usually be differentiated without instrumental means, and yet is frequently mistaken for a serious disorder. Extrasystoles may be associated and suggest auricular fibrillation. *Sino-auricular tachycardia* is a simple tachycardia associated with exercise, febrile and toxic conditions, and is usually regarded in its proper light. *Sino-auricular*

bradycardia with a rate of 50-60 may be a normal finding to confuse with heart-block. A study of the jugular pulse and a general examination of the patient will usually make the diagnosis. *Extrasystoles*, ectopic beats, or premature beats are also common, especially in young people, and usually have no great significance. They are often attributed to toxic influences or irritations arising outside the heart. In persons past middle life they are often associated with more general cardiac disease, and when arising from multiple foci, or when followed by alternation of the pulse, have more serious significance. When associated with muscle damage they may be forerunners of the tachycardias, such as auricular fibrillation, auricular flutter, or others. Extrasystoles arising in the auricles usually alter the rhythm of the heart, the new rhythm taking its time from the time of the inception of the extrasystole. Those arising in the ventricle usually do not disturb the underlying rhythm which takes its time interval from the last normal beat preceding the extrasystole. Extrasystoles may rarely be interpolated; that is, may fall between two normal beats without altering the rhythm. By listening to the heart, the extrasystole can usually be detected, which may not give rise to a perceptible pulsation at the wrist. This should be differentiated from dropped beats which belong properly under heart-block. By carrying the time with the foot, the changes in the underlying rhythm may be studied. By watching the jugular pulse in the neck, the presence or absence of the "A" wave may help to differentiate an auricular from a ventricular extrasystole. Extrasystoles frequently come in a definite sequence; that is, every second, third, fourth beat, and so on. If so, we may have a pulse at the wrist suggesting alternation, a bigeminal pulse, a trigeminal pulse, and so on. Exercise or anything which will increase the rate of the heart usually causes extrasystoles to disappear and give way temporarily to a regular rhythm. If the myocardium is severely damaged, extrasystoles may be increased by exercise. Electrocardiograms are of value in localizing the point of origin of extrasystoles and, when arising from multiple foci, would speak for grave disturbances. Multiple ventricular extrasystoles, associated with defective conductivity, may be forerunners of ventricular tachycardia and ventricular fibrillation, and indicate a bad prognosis. Chloroform anesthesia would be contra-indicated. Adrenalin should not be administered alone or in conjunction with chloroform anesthesia. By a careful study of the patient, the type and seriousness of extrasystoles can usually be determined. *Nodal rhythm*, where the impulse arises at the auriculo-ventricular node and passes in both directions, causes marked disturbance in the cardiac mechanism. Such a rhythm may be detected by a study of the jugular pulse. The rhythm is usually regular and rapid, but may be slow. The "A" wave in the jugular pulse may be present, coming close to the "C" wave, or may be submerged in it. The electrocardiogram gives a clear interpretation of this disorder, showing the site of origin of the impulse in the junctional tissues.

One of the commonest irregularities is *auricular fibrillation*. An electrocardiogram is seldom required to diagnose this condition. The absolutely irregular

rhythm, variation in force and volume, generally rapid rate (90-160), deficit between apex and pulse rate, absence of regular "A" waves in the jugular pulse, increase of the irregularity and breathlessness with exercise, and response to digitalis or quinidine differentiate this irregularity from others. A fibrillation, where partial or complete block is present, may be confusing. An auricular flutter, if showing an irregular ventricular rhythm, may simulate auricular fibrillation, but usually an underlying rhythm will be detected. Auricular fibrillation with slow undulating fibrillary auricular waves in the jugular pulse may suggest auricular flutter. The electrocardiogram is an aid in diagnosing these borderline conditions and in assessing the associated myocardial damage when taken in conjunction with the general clinical picture. With auricular fibrillation there is usually associated valvular or degenerative disease or toxic conditions, such as thyroid disease.

Auricular flutter, which is closely allied to auricular fibrillation, usually has a ventricular rate of 90 to 150, but may be above or below this rate. The rhythm is usually regular, but may be irregular. The auricles are usually beating about 300 times per minute and the ventricles fail to respond to each second, third or fourth beat because some of the ectopic impulses are blocked after passing through the auricles. The clinical symptoms are usually pronounced. The heart-sounds suggest a recurring irregularity or may be regular. The jugular pulse shows rapid regular "A" waves at about 300 per minute, with superimposed "C" and "V" waves. Vagal pressure usually causes a marked slowing of the ventricular rate when the "A" waves in the opposite jugular may be clearly noted. Exercise may increase the block and slow the ventricular rate. Quinine derivatives apparently have little effect on auricular flutter, but ample doses of digitalis may bring about auricular fibrillation which may then change to a regular rhythm if digitalis is withdrawn. Electrocardiograms are useful in exact diagnosis of the irregularity and in estimating the general muscle damage. Mitral disease and degenerative myocardial diseases are frequently associated. *Auricular tachycardia*, which is usually paroxysmal in type, generally shows a rate of 160-280 per minute. The impulses arising outside the pacemaker at the sinus take the center of the stage for a time and the heart beats rapidly and regularly. The clinical symptoms are generally marked, leading to anxiety on the part of the patient, family, and physician. Nothing can be determined at the heart except the rapid rate and regular rhythm. The jugular veins are distended and distinct waves are not easily made out. Anything which stimulates the vagus nerves may terminate the attack, in which case the regular, normal rhythm may be resumed in a spectacular manner. Quinidine by mouth or quinine intravenously may cause prompt cessation of the attack, which in itself is rarely fatal.

Any one of the disorders, namely, auricular fibrillation, auricular flutter and auricular tachycardia, may be paroxysmal in nature and, as such, probably constitute many attacks of *true palpitation* described by patients. Inasmuch as the attacks terminate promptly in a great majority of cases, clinicians

should be able to differentiate them without the aid of instruments because of the divergent prognostic and therapeutic features. Electrocardiograms show the location of the abnormal pacemaker in the latter two conditions.

Ventricular tachycardia is less common than auricular tachycardia, usually paroxysmal, and is a grave condition, occurring more often in extensive myocardial disease such as seen with coronary occlusion. The disordered rhythm with rapid rate and general condition of the patient leave little doubt in the mind of the clinician of the seriousness of the patient's malady. This condition probably precedes *ventricular fibrillation* which, if permanent, is not compatible with life. In both of these conditions, electrocardiograms are of value in instruction to complete the list of possibilities.

Heart-block may be noted in a variety of forms. *Sino-auricular* block is comparatively rare, where overstimulation of the vagus may cause the entire heart to stand still. Upon listening to the heart, no sounds would be heard and there would be no pulsations in the neck during the pause. This form should be differentiated from complete auriculo-ventricular block where the auricles continue to beat. Electrocardiograms may be necessary to aid in the decision. *Delayed conduction time* usually precedes the more severe forms of heart-block. The impulse from the pacemaker is delayed in its course from the auricle to the ventricles. A study of the jugular pulse will usually show that the "A" wave precedes the "C" wave by an interval greater than normal. Pressure on the vagus may increase the block. In many cases there are also dropped beats, where the ventricle fails to respond to an impulse coming from the auricles. The pause, indicating absence of ventricular contractions, may be detected by auscultation at the apex and noted in the jugular pulse. The pauses may occur rhythmically, tending to confuse with extrasystoles. An electrocardiogram is seldom necessary to differentiate, but is of value in showing the associated changes in the ventricular muscle. *Complete heart-block* may be permanent or paroxysmal in nature, as is seen in Adams-Stokes syndrome. The ventricles are usually beating at a rate of 20-50, but may show wider variations. The auricles are usually regular, but may show auricular fibrillation or flutter or other irregularities. There is no association between the rhythms in the upper and lower chambers of the heart. If the ventricular rate is slow, the auricles may be heard beating at a more rapid rate at the base of the heart. The jugular pulse usually shows the independent rhythm of the auricles; and there is usually evidence of degenerative disease in the heart. Syphilis, acute infections, and congenital lesions may be concomitant. By a careful study of the clinical findings, instrumental aids are not often necessary to decide as to the existence of complete heart-block. The original descriptions of Stokes and Adams are examples of the value of careful clinical observation. The blocking of impulses, which may occur in the bundles of His and its branches, and arborizations produce electrocardiograms which are, as yet, the least understood of all the abnormal mechanisms. The lesions which bring about such changes in the conductivity and contrac-

tility of heart muscles are often diffuse and variable, and the electrocardiograms produced thereby differ from characteristic curves shown by experimental study. We may not be able to demonstrate histologically the lesion which produces a given abnormality in the electrocardiogram. Clinically, we are not able to differentiate between a blocked impulse in the right or left branch of the bundle of His, nor are we able to state definitely that there is widespread interference with the impulse around the papillary muscles or beyond in the ventricular walls. The electrocardiographic method is invaluable in estimating the significance of some of these grave disturbances. The interference of the conduction of the impulse in the ventricles will be shown. The shape and duration of the "Q, R, S" complex and the shape and deviation of the "T" wave will give us an idea of the extent of damage. The general condition of the patient may suggest a grave cardiac condition. The poor quality of the first sound or the split first sound at the apex of the heart may be the only abnormality noted on general examination. Pulsus alternans may be noted when taking systolic blood-pressure readings and rarely by feeling the radial pulse in marked cases. Polygraphic tracings may reveal constant alternation or only after extrasystoles in such cases, and would be a help in diagnosis and prognosis.

The nature of *pulsus alternans* is not fully understood, but of its seriousness there can be no doubt. This is one condition where the electrocardiographic method gives us very little help, unless we can show changes in the ventricular complex which, in themselves, are known to be of equal seriousness and significance.

In *irritable heart*, strong respiratory cyclic oscillation of the electrical axis with sinus arrhythmia may be of assistance in making the diagnosis.

Relative *hypertrophy* or *preponderance* of one side of the heart over the other may be shown by the electrocardiographic method. The findings may be of value in a study of congenital or valvular heart disease, hypertension, and nephritis, but should be used only in conjunction with the general clinical and roentgenographic findings. Changes in the "P" waves may indicate unequal hypertrophy of the auricles.

In considering the disordered mechanisms of the heart from a diagnostic standpoint, it should be kept in mind that combinations may occur which make accurate diagnosis almost impossible without the assistance which the electrocardiograph may render.

VALUE IN PROGNOSIS

The electrocardiographic method has proven of great value in prognosis. This is largely due to the fact that recognition and classification of disordered mechanisms by this method enabled us to study the various groups over a period of years. Apparently, all the possible cardiac disturbances have been observed experimentally and clinically. As a general rule, individuals who show multiple disturbances in the normal cardiac mechanism, as shown electrocardiographically, have a grave prognosis. Those who show simple extrasystoles or sinus arrhythmia

have an excellent prognosis. Paroxysmal auricular tachycardia is usually not of a serious nature. Auricular fibrillation is often paroxysmal and not serious, but when permanent is usually attended by increasing disability because of the frequent association with a failing heart muscle. Auricular flutter parallels auricular fibrillation. The finding of bundle-branch block or arborization block, which may be shown only by the electrocardiogram, usually indicates a grave prognosis unless syphilis be the etiological factor. Changes in the "T" wave, especially inversion of the "T" wave in Lead I, Leads I and II, or Leads I, II, and III combined, are known to be of serious prognostic significance, providing digitalis has not been recently administered. Ventricular tachycardia and ventricular fibrillation, which can be definitely diagnosed only with the electrocardiograph, are grave conditions, the latter usually being observed only in the dying heart.

VALUE IN TREATMENT

As in prognosis, the value of the electrocardiographic method in treatment of heart disease is still in the academic and developmental stage. The action of certain drugs like digitalis, strophanthin, quinine derivatives, arsenicals, atropine, physostigmine, adrenalin, potassium salts, muscarine, aconitine, and others is being better understood because of careful experimental and clinical electrocardiographic studies. The effect of digitalis on the "T" wave may be studied during treatment to insure the desired therapeutic effects, or the observations may be used as a method of standardizing the drug. Before giving quinidine to restore a fibrillating auricle to a normal rhythm, it is well to know something about the ventricular muscle. If the patient is suffering from extensive myocardial damage and congestive heart failure, it would be unwise to proceed with such treatment until the congestion had been cleared up with rest, depletion, restriction of fluids, and digitalis. It would probably be unwise to employ quinidine if the heart muscle shows extensive damage. The electrocardiogram would be of value in making our final decision about treatment. In heart-block due to syphilis, the progress of the treatment with arsenicals and iodides can be readily shown by electrocardiograms. Patients with heart-block who are taking atropine may have the progress of treatment carefully checked by this method. As time goes on, no doubt other avenues of study with the electrocardiograph in therapeutics will be revealed and older methods will be abandoned as a better clinical understanding is established.

SUMMARY

The electrocardiographic method has served a useful purpose in clearing up much of the mystery concerning disordered mechanisms of the heart. The close parallelism between experimental and clinical observations affords the most brilliant example of applied physiology up to this time.

The electrocardiograph, with such modifications as may be made, will remain an instrument of great value to the investigator. Its permanent place in medical education is assured, for study and research

and in the instruction of successive classes of students.

All medical students should be taught the interpretation of the commoner types of electrocardiograms, and they should be instructed to recognize most of the disordered mechanisms of the heart without the aid of any instrument of precision.

Practitioners who have not had the advantage of instruction in the use of the instrument and what it reveals should make an effort to learn the commoner types of abnormalities. Polygraphic study will be of assistance if an electrocardiograph is not available.

The electrocardiogram serves as a permanent record for comparison and study.

The value of the electrocardiographic method in prognosis and treatment is great, but will not be fully realized for many years to come.

Finally, it should be remembered that the electrocardiographic method is an aid in clinical medicine to confirm the findings of the physicians, and to stimulate him towards improved methods of observation.

Serologic Significance of Streptococci in Arthritis and Allied Conditions—In using active serum, R. Burbank and L. G. Hadjopoulos, New York (*Journal A. M. A.*), have developed a technic for bacterial fixations, in the main of the streptococcus types, whereby various arthritic and rheumatoid conditions may be classified serologically into three major groups: Arthritis reacting to hemolytic streptococci and belonging to the iso-atrophic class. This type in pure form is periarticular. Arthritis reacting similarly to hemolytic streptococci, but of different fixing properties. This type is aniso-atrophic or deformans. Arthritis reacting to streptococci of the *S. viridans* type and belonging to the osteoarthritic or productive form. The bony change is often a very early manifestation in this group, and is demonstrated by crepitus and by roentgen ray. The majority of arthritic cases that are not arrested or cured early in the course of the disease have a tendency to undergo further changes leading to mixed types. Thus, in an acute exudative periartthritis or in an arthritis deformans, the bony parts gradually may become involved and give rise to a mixed serologic picture. Similarly, in a chronic productive arthritic case, acute tonsillitis, or some other hemolytic infection may engraft a synovial (hemolytic) flare-up on a chronic hypertrophic joint. A fair percentage of arthritic patients, especially those suffering from colitis and chronic constipation, have a marked tendency to effect complement fixation in certain strains of non-hemolytic streptococci isolated from the intestinal tract of similar arthritic cases. This type of organism seems to be a transition form of streptococcus hemolyticus, with certain properties lost through secondary intestinal implantation. Certain pathologic conditions have long been known clinically to be precursors of arthritis. Serologically, we have confirmed these clinical observations. In controlling the value of the test in normal cases, the possibility of the presence of some masked focus of infection must be considered. With this point in mind, the test is not diagnostic for arthritis alone, but is diagnostic of a wide group of acute and chronic infections that give rise to anti-streptococcic bodies in human serums.

CONDITIONS, ESPECIALLY PREVIOUS PATHOLOGICAL CONDITIONS, WHICH INTERFERE WITH RESULTS IN INDUSTRIAL INJURIES

By S. J. HUNKIN, M. D., *San Francisco*

Previous conditions, arising out of earlier injuries or already existing diseases, may and often do materially modify results obtained after industrial injuries. Outside of osteo-arthritis and probably the major fraction of even this, the most important cause for previously existent structural pathology of the working man, lies in the long continued exposure to the elements, the faulty, oftentimes necessary, positions, the frequently repeated minor injuries occurring perhaps over a great many years.

The last accident is oftentimes not the one important factor in the disability.

DISCUSSION by J. Rollin French, *Los Angeles*; J. L. Pritchard, *San Jose*; Frank M. Mikels, *Long Beach*.

A PATIENT, beneficiary under the Industrial Accident law, came to see me regarding some patches of eczema on his right lower leg which, he alleged, came from a plaster splint applied by me more than a year and a half before and for which he claimed compensation. He exhibited several patches of a weeping eczema on his right lower leg. I had examined this man on an average of once a week for many months up to some two or three weeks previously, and knew during this time he had no suggestion of eczema. While examining the leg, I noticed a stain on the other stocking and asked him if he had any eczema on the left leg. He denied the allegation, but when I pulled down the other stocking, I found a patch of eczema about as big as a silver dollar. This particular patient came under my observation about one and a half years ago with a mal-posed fibrous union fracture of the upper right femur. We noted at that time a deformity just below the right knee which he said was from an old fracture. We also noted a mal-united overlapping fracture of both bones of the lower third of the right leg which he said dated from a fracture some fifteen to eighteen years ago. At the time he came under my observation he had a peculiar tumorous growth around this mal-united fracture which had given rise to the suspicion of sarcoma. He has made a very good recovery; has good union, although radiographically the recession of the old tumor suggests a duplication of the repaired shaft; he has practically normal motion in the hip-joint; and has a flexion of from 115 to 120 degrees in the knee, with a shortening of between two and three centimeters. He now claims compensation for lessened motion in the knee, a shortened leg, and an eczema of one leg (having it on both), all as a result of the last accident. It is apparent to any man having experience with fractures that the previously existent overlapping fractures in two places must of necessity have given a shortening probably equal to what he at present has. It is also evident that a fracture with deformity within a centimeter or two of the knee would lessen the motion of that knee in some degree. I shall be interested in what compensation will be given. All of you who deal with such cases must have an idea of how much his present disability, including the eczema on one leg, is due to the accident in question,

and must ask yourselves "how much did the previous pathology modify the result obtained after the last accident."

At present there are under my observation two men, the conditions of whom are closely similar: the one a state compensation case, and the other drawing compensation from another insurance company. Each one received a minor injury to the heel—I say minor because good and repeated radiograms, before they came under my observation and afterwards, disclosed no evidence of injury. They both present spurs and inflamed bursae. Both show definite arterial vascular changes, and the one has a Wassermann XXX. The one has lues with a probable Neisser symbiosis, and the other has a definite Neisser with a probable spirochete symbiosis. Similar injuries sustained by a normal individual would probably have caused soreness, possibly a little lameness for a few days—at the outside say for two or three weeks. In both of these cases the motions of the ankle-joint and tarsus are practically normal; yet each man complains of pain, marked disability out of all proportion to the evident pathology, and both are definitely intent upon getting a life ticket upon the insurance funds. One of them, the positive Wassermann man, has lately claimed extra compensation because of trouble with the other foot, and suggested "beginning ventral hernia." Beyond doubt, in these cases the injury plays only a very minor role and certainly is not responsible for more than a minor fraction of the disability claimed. The worst feature about such cases is that some members of our profession help them in their pretensions, by seriously considering and detailing symptoms which they admit have neither pathological nor structural basis, but honestly argue that "their need is great"; that "the employer takes them as he finds them"; and that "the insurance company has plenty of money and takes premiums on that premise." As I see it, charity, the saving virtue, has as its only limit and only requirement the need therefor. Compensation, on the other hand, is not charity and must be considered solely as giving "pro for quod." Compensation is paid for and the insurer seeks nothing, but demands only what has been paid for. The need of the sufferer, the richness of the company plays no part. The employer does not "take the employe as he finds him," as I see it: he oftentimes does not take him at all, but has him thrust upon him, and at times has a well-known lame duck sneaked upon him. I have known a strike called and later called off on account of certain men, it being well known to me—and, of course, to many others—that these particular individuals who had not been doing the proper stint of work and in the settlement must be taken back were lame ducks and not able to do their proper stint of work. The employer in this case does not take them as he finds them, but has them thrust down his throat. It is not rarely my experience to have a man under my care or sent to me for an opinion of his condition, the result of an alleged accident, when I had treated the man for the same symptoms months or years before the alleged accident. I have also had men refuse to be sent to me who later have admitted to me when the case was settled or when they were forced to come to me that they expected I would

give some information regarding their previous condition. Sometimes the necessity is great; sometimes the love of a much-needed rest is greater, and once in a while the recognized necessity for slowing up is greatest. That money should be taken from him who hath and given to him who hath not, is hardly a valid argument excepting in idealistic Christianity; in the Soviet land; or in thieves' quarters: yet, a somewhat parallel idea is not rare among real and practical people regarding the money of other folk. It is suggested that the origin of many of these ills of previous conditions arises in the course of a man's employment; that the employe has been worn out in industry—if not in the last few months, then in the last few years; that the essential factor in the increasing disability primarily results from his labor, and, therefore, there should be a tax upon industry for the support and protection of one broken by industry, and time as a factor should not be of the essence of this understanding or argument. I believe this argument and this idea to be true, and labor along these lines has a just grievance. I recognize and assert that laws must and will be made in the nearby days to cover and remedy this present failure. Such conditions arising should be a tax upon industry and such pathology arising out of the character of employment, even going back ten, fifteen, or twenty years maybe, should be paid for, in my opinion, by industry. This is right, square, and equitable, and such an arrangement in the end must and will prevail: yet, this has nothing at all to do, as I see it, with the present status. There is at present no way to levy such a tax covering various industries (perhaps long extinct) of the past twenty-five years, more or less. As a matter of fact, we cannot make a law so retroactive. You can hardly levy on me to compensate one for something that my grandfather should have attended to, although at that time no such idea had arisen, and certainly cannot ask me to pay for what my grandfather's dearest enemy had either accidentally, thoughtlessly, or even wilfully neglected. There should and will be found some method to take care of such persons in the future, and there is no better time than the present to begin. Certainly, this will be seen more and more clearly in the future, and great business will neither expect, hope, nor be permitted to prosper by using up or breaking up humanity as has too often been the case in the past. Two cases confront me now along this line: A plasterer, a very expert man, for many years has worked chiefly at overhead ornamental work and has become very skillful thereat, thereby earning extra money above his craft. He has developed, most probably as a result of the necessary continued vertebral hyperextension, a potential and probable steadily increasing spondylolisthesis. In this condition and position, about a year ago a twist gave him a sacroiliac strain for which he claimed and received compensation. He recovered from the strain, but the tendency towards spondylolisthesis steadily increasing with his years and weight, he finds that he can no longer, with any degree of security and comfort, do the special work which calls for vertebral hyperextension. This, however, is what he does best, what he feels he is best fitted for, and what pays him the most money. This potential spondylolisthesis, how-

ever, in my opinion, is a pathological condition engendered chiefly by his occupation and dependent upon the industry he has been engaged in. The issue is plain and simple to me and I am keen to know how the commission is going to decide, for they have no easy job in this and in similar cases. They are making precedent and history in their work of today, and what they are now deciding shall rise to comfort or plague them hereafter. Here is another case along these lines in which the scales of justice will be hard to balance, and it will take a Solomon to give an unquestioned judgment.

An honorable man well advanced in life has for a great many years worked at heavy, highly skilled mechanical work. For some time for three reasons—advancing years, a little stiffening, and favor of his employers for an old, steady and efficient worker—he has been given light work. During this work (the man himself feeling vigorous, perhaps not appreciating his gradually lessening capacity) he received two slight accidents (several weeks apart) to his elbow. After the second accident he finds, apparently to his surprise, that he can no longer wield the tools of his trade. Several weeks elapsing without recovery, he seeks other medical advice, and it is found that his elbow has less than half normal motion. Loose pieces of bone and irregular masses of bone are found by the finger and in radiograms in and around the elbow. The man has had an osteochondritis, endochondritis dessicans if you prefer, over many years, and the slight accidents, while probably producing the suddenly noticed symptoms, are merely an incident in the history of the lamed joint. The accident, in my opinion, should not be held even as a major cause. The occupation, on the other hand, was the major factor. What is the answer? How and who shall compensate? Another man, a structural worker, was under my care years ago with a fracture in the upper third of the left femur. The fracture at that time was readily reduced and held with a metallic suture, which, by-the-by, is still in situ. He recovered with normal function and has been working as usual up to the last accident. At the time we first examined him, we noticed an old overlapping fracture of the left clavicle and a suspicion of a fracture of the right clavicle. Some three months ago he fell and shattered the right humerus in the surgical neck; fractured the left tibia at the internal margin into the knee; and also the left fibula into the left ankle. He is again making a good recovery and apparently will soon be again about his work. However, he has had five important fractures of long bones, to my knowledge, and each one lessens his normal a little bit. He is getting by well, however, and probably does and will consider himself normal. However, looking into the future—suppose he has a few more fractures during the next ten years, each one taking a little from him. He will then be over the active period of life, but perhaps will still have the will to do, or more likely be forced to do, and perhaps now gets a comparatively mild injury to his hip, knee, ankle, or shoulder. He may have disability out of all proportion and possibly out of all relation to his accident, and comes before the commission for justice. How are they going to apportion it? Still, his dis-

ability is directly traceable to his work and in my opinion, of right, should be a tax upon industry; but to what accident should it be apportioned? And what insurance carrier should justly pay the tax under our present law? A tax upon industry, we say; but upon what industry, and where? Here is another one: A Russian, 48 years of age, who had lived in Russia up to the last two years, going through the war with all its hardships and vicissitudes. Since he has been here, he has been a laborer and within a few months gets a slight fall, injuring his back. After a few days he resumes his work, but says his back troubled him. The discomfort or distress or pain gets worse and worse and he lays off from work. Radiograms taken at this time, not by me, show a very extensive osteoarthritis of the spine with spurring, bridging, and mushrooming. This condition, we know, must have existed, gradually increasing for many years. He has a progressive disease, hastened probably by the slight fall, but destined to develop, regardless of any fall, and be eventually disabling, especially if, as in this case, the man believes he has a "meal ticket for life." In this case the back was not normal, he suffered some from it, and very possibly, even probably, the slight injury had exaggerated the symptoms; in fact, may have called the stiffening to his attention. The man was not entirely disabled—on the contrary, was able to do a reasonable amount of work for years if he had the will and desire to do so. He needed some help and as time goes on will need greater help, and naturally will have greater and greater disability as time advances. He had a wife and children and appeared honestly to believe he was entitled to full compensation. He came to me outside of the insurance company for an opinion towards getting greater compensation. The injury, however, in my opinion, was perhaps responsible for 10 per cent or at the most 20 per cent of his disability; perhaps not responsible for any of it. Who should pay the compensation his family needed, and which he strongly felt and was advised he was entitled to—the employer for whom he worked a few days? the Russian Government for whom he struggled and slaved for twice as many years? Whose industry should be taxed—American or Russian? Civil or military? It may be that all men are brothers under the skin, but why flay John Jones because the hide of Ivan Ivancovich was tanned? Many such cases have presented themselves: Mexicans, Slavs, Cubans, and Europeans, in whom it was evident that their structural condition was such before they entered this country that a simple examination could have determined that their disability was imminent and when occurring would probably be severe and lasting. Previous pathology modifies results perhaps more after injuries to backs than after injuries to any other structure. As a fact, previously existing pathology in backs is probably responsible for most of the economic waste occurring to the insurance carriers under the compensation law. They not alone take much more compensation than they are equitably entitled to, but to a very great extent increase the medical expense of the insurance carriers. Most of this excess is due to previously existing pathological changes, osteitis and periostitis chiefly. To a

lesser degree perhaps it is augmented by a desire on the part of a man who is advancing in years to escape the daily, strenuous treadmill of modern industrial life, and not a little perhaps, to the doctors under whose care they come, and to the oftentimes multiplicity of doctors whose advice has been sought by the patient and the insurance carrier—by the former to get symptoms relieved if possible (and they often doubt this will be done), but if not, to at least have their symptoms discussed, accepted, explained, and put over to the commission—by the insurance carrier to get rid of apparently never ending worry and expense, and to secure explanations and opinions which will enable them to get what appears to them to be a reasonable rating. It has more than once been my duty to examine a man for disability resulting from an alleged injury to his back or to his sacro-iliac area after I had had the privilege of treating him for similar symptoms years before, resulting from a similar accident, and had issued the warning then that a recurrence would probably occur under such and such circumstances. I have suspected, even known at times, that the relapse or recurrence was deliberately provoked because the man was tired of not being able to do a heavy day's work against his partner, and knew he was getting older all the time and soon might not be able to hold down any job. I have been cognizant of this in several cases, and have suspected it (or rather known it as well as a man knows anything that he has not himself observed) in several scores of cases.

It is not wise, speaking solely from the standpoint of the patient, in a case of injury to a back, complicating a vertebral osteoarthritis to be examined by too many doctors. In a multiplicity of counsel there is not necessarily wisdom—much more often the reverse of wisdom. Just as often as "too many cooks spoil the broth" do too many doctors hinder the recovery of such patients, and this for two reasons: First, it gives the patient's conditions and symptoms an undue prominence and emphasizes the readily acquired idea that the condition does not permit of recovery; and second, no two doctors express themselves in similar language even when agreeing upon the condition, and this difference in expression oftentimes impresses the patients as difference in opinion. (It must have occurred to you, as to me, when the patient was told that he had a fracture to have his reply: "Dr. Blank told me I only had a break"; and on such a statement (that is difference in words used) the patient bases the idea that the doctors did not agree about the case.) Harm comes to the patient and expense to the insurer by way of the doctor in another way: a multiplicity of opinions mixes things up and generally favors a compromise treatment. With no one satisfied and no single plan properly carried out, wisdom is not found, and a definite plan of treatment is not carried to success along such lines. Many a promising case is ruined, treatment greatly prolonged, expense vastly increased, and worse than all, the patient demoralized and dropped below the level by too many opinions. Better a mediocre plan carried out in detail than a compromise of many better plans, no one of which gets a complete trial. I think it is in this way that insurance carriers may get an advantage from a staff

of their own, probably of second-rate men, for although the particular plan of treatment may not be so good, it is taken care of in detail.

Speaking of pathological conditions, results, treatment, and multiplicity of opinions, I would like to put myself on record as saying that, in my opinion, too much stress is laid by the doctor upon the history and statement of the patient in structural damages rather than upon conditions found. In my opinion, the examining surgeon should examine a patient as an engineer a bridge, and make a report of what conditions are found, paying only secondary attention to the statements of the parties in question, not because necessarily there is intent to mislead, but rather because the injured man does not know, and mixes imagination, memory, and reasoning in his tale. It would be cheaper, and so far as I am concerned, often of just as much avail to both parties if the history were taken by the stenographer in the insurance office. After all, one is dealing with a structural condition which may be determinable, and not with theories, stories, or opinions. I have digressed somewhat, and ask your pardon for the digression, because it appears to me that "plenty talk" on the part of the doctor or doctors is responsible for delay and the gradual infiltration of the patient with the feeling that he has suffered much, and much is coming to him. In this frame of mind he is not likely to admit previous disability—in fact, the recollection of the past is overborne by the pain of the present and the question of the future. I well remember a horseshoer who was sent to me with recent infected fractures of the lower leg. Noticing a kyphoscoliosis of the third degree with a marked psoas contracture, and appreciating the possibility later of the back conditions being blamed upon the infected areas, I had him well radiographed and a careful detail of the hip and back contractures and positions made. A good recovery was secured from the fractures, and the man was probably afterwards in practically as good condition as before his accident, yet he claimed disability from shortening of his leg and inability to straighten his hip-joint (due to the previously existent psoas contracture secondary to the deformed back). By telling his story well himself, apparently believing most of it, and getting some members of our profession honestly to support him, he gets a rating of 32 per cent. Really the man was disabled, perhaps 32 per cent or more, although I doubt it, but approximately nine-tenths of this disability existed prior to the accident and was, as I see it, not up to the insurance carrier. The man is now a great friend of mine, although I stood against him at the settlement, and again is engaged in mechanical work (not horse-shoeing) and making more money than he was before. Surely, the gods favored him in slipping him such a fortunate accident at a time when his months were numbered as a horseshoer. The employer took him as he found him, and found "some lemon." This is a type of man, and not the very worst, that has come under my observation, and I am using it (of course, because it is a well-marked case)—if not to point a moral to at least adorn my tale. Take the picture of his back and hips as they appeared at the time of the injury, not after the infection had spent. Many of you have

seen similar cases spurred, and bridged, and even fused with periosteal outgrowths which extended away from the vertebrae more than a centimeter, locking and interlocking, this condition showing within a few hours of the accident, mind you, so that one could approximately measure the previously existing and gradually growing pain, stiffness, and disability, in spite of all statements and evidence which might be and was offered by the applicant. Many years, you will appreciate, it must have taken to develop such extreme changes, the causes being drink, exposure, hard work, and last but not least, repeated gonorrheas. There is an old adage, perhaps once true, that "Those who dance must pay the piper," and again from the sacred writings—"What ye sow that shall ye also reap"; but in this case the sowing of the whirlwind brings to him, through the beneficence of the law, balmy ease and comfort as he approaches the autumn of life. I tell you he appreciates that accident, and because of his friendship to me I rejoice in his good fortune, reached, as stated in the biography of Mr. Raycroft, "through no work nor virtue of my own." The arguments usually offered and oftentimes worthy of all credence that "he worked before at the same place for ten years without a lay-off by reason of sickness, previous to his accident" means no more than the statement of the hotel-keeper in the backwoods who, when a guest sought a clean roller-towel, exclaimed: "Well, dang it, sixty-five men used that roller this morning and you are the first one who complained." Going on the ferry a few months ago, my attention was called to the piles at the dock. A great many were eaten away, coming to points like sharpened pencil-ends meeting. A few even were parted; yet, the dock stood. The boats went in and went out, bumping on the sides day after day, the piles withstanding the blows, and one stood and wondered. A short time later I saw in the paper that this ferry was out of commission because a boat had hit the dock a glancing blow and it had caved in. It is possible that the last blow was not nearly so hard as the dock had had previously; and daily and hourly resisted, yet the argument that, because of the earlier daily known work, it must have been all right previous to this last blow, is not valid to the engineer who sees the extensive pathology and knows the teredo has been doing his work for years before—in short, the wonder was not that it fell with this particular blow, but that it had withstood the blows over the days and weeks and months before.

In conclusion, it is my desire to emphasize the following: That previous conditions, arising out of earlier injuries or already existing diseases, may and often do materially modify results obtained after industrial injuries; that outside of osteo-arthritis and probably the major fraction of even this, the most important cause for previously existent structural pathology of the working man, lies in the long continued exposure to the elements, the faulty, oftentimes necessary, positions, the frequently repeated minor injuries occurring perhaps over a great many years. The last accident is oftentimes not the one important factor in the disability. Of right, the gradual using up and wearing out of a man in industry should be just as compensable as his breaking up. Laws must

be made in which the time factor is not of the essence of the understanding—that a date is not important in the using up of a man's structural capacity. A new deal and a new understanding is at hand.

It is true that a little real malingering is being put over, but very little. It is true, however, that a good deal of exaggeration is being put over. Probably the chief cause for this is the feeling that telling the truth about the pre-existent and growing disability mitigates against compensation. If previous conditions oftentimes were accepted as evidence of a using up in industry and were made compensable, the great incentive for exaggeration would pass and a better era between the laborer and the employer would be inaugurated. The time has arrived. Broader vision is necessary for the future. Other laws, wider outlooks, are imperative.

1155 Bush Street.

DISCUSSION

J. ROLLIN FRENCH, M. D. (417 Towne Avenue, Los Angeles)—I have read Doctor Hunkin's paper with much pleasure and interest. The doctor ably deals with some of the most serious problems of industrial medicine. I have examined and directed treatment in many hundreds of cases, such as the variety the doctor describes, and well appreciate the perplexities.

From my experience, I have formulated a definite procedure as to diagnosis and management. I am convinced that it is just as important to make a psycho-analysis of the mental aberrations of the patient as it is to diagnose the osteo-arthritis of the vertebra. I most heartily concur in the statement that "It is not wise to have the patient examined by too many doctors." It is surprising how soon some of the seemingly ignorant patients pick up medical phraseology and subjective symptoms therefrom. Perhaps, I can better express myself by defining the varieties of malingering. First, let us divide them into true and false malingerers. A true malingerer is one who, with malice aforethought, feigns for gain. This type, as a rule, are not difficult problems. The false malingerers are those who misinterpret existing symptoms and feel they will do themselves bodily harm if they attempt to work, when, as a matter of fact, they are doing themselves bodily harm by not working. The skilled diagnostician well realizes that work, in many instances, is the best treatment, but he overlooks the importance of psycho-analysis and hence is unable to sell the patient the idea. We sometimes condemn the patient for not understanding and going to work, when, as a matter of fact, the physician should condemn himself for not having the ability to successfully teach or sell the idea, which would result in co-operation.

I do not always blame the ignorant mind for thinking that perhaps eczema is the result of an injury. The patient does not know the etiology of eczema (?). With a few exceptions, I have found that a simple explanation frequently transfers cases of this nature from the compensable class. I believe we should give some consideration to the fact that the average layman knows but little relative to the subject of pathological etiology; therefore, we should have more patience in explaining same. To reverse the situation, I will relate a conversation between a doctor and the manager of an automobile agency. The doctor had but little knowledge of mechanics. He was having difficulty in keeping his automobile running smoothly, and, after repeated visits to the adjusting department, he called upon the manager and condemned the car as not being satisfactory, and intimated that he had been sold a lemon. The manager, instead of completing the sale by educating the doctor in the successful operation of the car, lost his head and told the doctor "he was selling automobiles and not brains." It is needless to say that that automobile concern lost a customer. Successful men in any profession are those who can sell ideas successfully.

Nature is most accommodating, and if we sell the idea

of co-operation to our patients, nature will compensate, in many instances, the deformities or pathology by re-routing function.

I believe "Take the employe as he finds him" is worthy of greater discussion than space here permits, and there are many good points for and against.

With reference to the cases of spur of the os calcis, no doubt the psychic damage causing prolonged compensable disability was caused by the doctor who preceded Hunkin. Had the first doctor definitely and positively diagnosed the cause of disability and so explained and sold the idea to the patient, compensation would have suffered but little beyond the expense of the original examination. The patient, perhaps, was in good faith when he thought the slight accident caused the disability, but negligence on the part of the attending physician to explain the true cause of disability further prompted the patient to accept the slight injury as the cause of disability. Self-preservation is the first law of nature. I have even heard physicians exaggerating circumstances when applying for replacement of an automobile tire or surgical equipment. Perhaps, the physician was in good faith, but for lack of knowledge upon the subject was apparently claiming something to which he was not entitled. These circumstances parallel injured employes attempting to obtain compensation payment. I believe it is the physician's duty to exercise every reasonable effort to educate the patient when he, the patient, applies wrongfully for compensation benefits. If after exhausting his resources in his effort to convince the patient of the true etiology of disability and that his disability is not compensable, the physician finds he is not successful, then, in my opinion, it is his duty to collect all possible evidence in tangible form to prove same before the Industrial Accident Commission. Physicians at times are so endowed with the idea that their diagnosis is correct and they frequently lack the legal training of preparing evidence for a decision by another.

In conclusion, I wish to state that I believe Dr. Hunkin's paper has ably and forcibly brought out the urgent necessity of several points in the management of patients with previous disease due to industrial injuries:

The importance of an early and positive diagnosis as to the true cause of disability.

To more carefully weigh subjective symptoms.

The necessity of better and more positive salesmanship on the part of the physician after making a differential diagnosis.

The necessity of greater knowledge of law and contract by the physician.

The importance of psycho-analysis in differentiating between true and false malingerers. The value of accurate evidence in which to supply a judiciary when it becomes necessary to settle differences of opinion.

J. L. PRITCHARD, M. D. (Twohy Building, San Jose, Calif.)—Doctor Hunkin has definitely pointed out some salient features of a situation which many times is embarrassing and often humiliating for the physician. Are doctors to blame for many unseemly occurrences in cases before the courts and industrial accident commissions? It is not unusual to hear a layman say that one may get a doctor to testify to anything, and everything. If that is a correct statement of prevailing conditions, then it is no wonder that the injured malinger. If they do not do it of their own free will, they often have it thrust upon them.

In most features the industrial situation is very similar to that of the disabled soldier. If a man was accepted as sound at the time of enlistment, any disability arising would be considered as "due to service," although it might be osteo-arthritis, sacro-iliac strain, or what not. Many industrial organizations insist on their employes passing an entrance physical examination, and more than that—a check-up yearly or semi-yearly.

FRANK M. MIKELS, M. D. (Long Beach, Calif.)—After reading Doctor Hunkin's paper, I am very much impressed with the salient and important facts which he has presented relative to pathological conditions existing previous to industrial injuries and subsequent psycho-neurosis following physical traumata.

The attending physician is under a moral obligation to

render to patients that order of therapeutic procedure which will restore them to as near normal condition as possible with the highest degree of function. He must use extraordinary tact in his discussion of existing pathological conditions, when satisfying the curiosity and demands for information, not only from the patient himself, but also the members of his family. The implantation of morbid ideas through suggestions into the psyche or consciousness of a severely injured patient may often lead to fixed mental morbidities which may play a great part in impairing the normal function of his injured limbs or other parts of the body. Functional psycho-neuroses following severe joint, tendon, and nerve injuries, are often responsible for a great degree of the disability resulting from such injuries, and sometimes from very slight trauma.

It is very difficult to fix the degree of relative causation when neuropathic conditions develop subsequent to a series of industrial injuries extending over a period of several months or years. The object of paramount importance is to get away from the dogmatic discussions and the diagnostic hypotheses and settle down to the practical application of more recent methods of physiotherapy, such as deep therapy, diathermy, galvanism, faradism, mechanotherapy, massage, and the other kind of physical or mechanical readjustment that will clear up the complications subsequent to various injuries.

The time has come when the industrial surgeon and physician must recognize the true value of these recent therapeutic agencies and apply them properly in degree and modality, as indicated in each individual complication or pathological condition.

The psycho-neurotic personality may maintain a normal degree of occupational efficiency until he meets with a physical injury attended by psychic trauma. Following in the wake of the psychic trauma may come metabolic disturbances, manifested by recurrences of asthma and eczematous manifestations. Paralysis may develop which has only a psychic basis. A latent thyro-toxic condition may be aggravated and accentuated as a result of the emotional shock attending physical injury. It is not unusual for a cardiac myasthenia of the neuropathic type to manifest itself and thereby incapacitate the injured employee for a long period of time.

The state compensation law contemplates protecting the employee against disabilities arising from existing pathological conditions which may be aggravated by an industrial injury. Having this premises as a basis of medico-legal relationship with the patient who has met with an industrial injury, the physician in charge finds himself in a very delicate position, requiring extraordinary judiciary consideration as well as medical and surgical acumen.

And Still Some Who Promote Charity as a Business, Accuse Them—The doctor is one of the few professional men who gives his service free to the public. The doctors of the United States give away about \$1,000,000 worth of service every day in the year to the indigent and to those who do not pay bills.—Chicago's Health, February, 1925, "The Physician."

"The Physician as a Sanitarian"—Every physician is a guardian of the public health, and the community expects him to be interested in medical matters of a public nature, just as they expect the lawyer to take part in the legal aspects of public affairs, or any other citizen to contribute his best thought upon public questions. The opportunities and influence of the physician as an educator are greater than those of almost any other group. Many have implicit confidence in the word of some physician, and the attitude of the public toward public health matters is to some extent a composite of the attitude of the physicians of the community.—Chicago's Health Bulletin.

MALIGNANT TUMORS OF THE KIDNEY

WITH SPECIAL REFERENCE TO DIAGNOSIS

By FRANK HINMAN, M. D., AND ADOLPH A. KUTZMANN, M. D.

(From the Department of Urology, University of California Medical School, San Francisco)

The incidence of malignant tumors of the kidney are to the extent of 0.25 to 1 per cent in adults; 0.06 to 0.1 per cent in children. Of tumors in general, they constitute from 0.5 to 2 per cent in adults and about 20 per cent in children.

The pathogenesis of kidney tumors is still in the hypothetical stage. The types most commonly found are the hypernephroma, occurring chiefly in late adult life and "embryonic mixed tumors" found during early childhood.

Clinically, all renal tumors should be considered malignant because of the great rarity of the benign types.

The classical signs of kidney tumor are hematuria, pain and tumor. Hematuria is the most frequent initial symptom in adults, while tumor is in children.

The importance of each symptom should be considered initially as it appears and the diagnosis not allowed to wait until the clinical picture is complete.

Only by thorough early investigation can we hope to influence the present appalling morbidity of 90 per cent.

The urological examination should always be complete and include a differential examination of the urine, functional studies, and ureteropyelography.

The correlation of the clinical findings and urological findings should be carefully entered into so that a diagnosis may be arrived at in the doubtful cases.

DISCUSSION by George F. Schenck, Los Angeles; Nathan G. Hale, Sacramento; Paul A. Ferrier, Pasadena.

THE surgical problem of care of malignancy any place in the human body has two very important and fundamental points: (1) An accurate diagnosis made early enough, (2) to make possible a complete and permanent removal of the tumor. Application of these principles in treating malignancy in some parts of the body has most markedly lowered the mortality. The breast, uterus, and mouth are notable examples, and the fact that metastases in these conditions occur primarily along the draining lymphatics which are surgically removable, still makes possible a small percentage of cures even in those who seek aid in the later stages of the disease. Thus Bloodgood has found, in thirty years' experience, that cancer of the tongue when gotten in the early stages yields a cure in 62 per cent of cases, while only 12 per cent are relieved in the later stages; in breast cancer, 70 per cent may be cured if treatment is sought as soon as the lump is felt, 25 per cent if the lower axillary glands have become involved, and only 10 per cent with the involvement of the higher axillary glands.

In malignancy of the kidney the problem is similar but more difficult, particularly respecting early diagnosis, and more radical surgery than nephrectomy has never been successfully advocated. There are really no pre-cancerous or early symptoms in kidney tumor. A. O. J. Kelley, in 1895, showed that 72 per cent of cases came to autopsy undiagnosed, in spite of advanced liver and lung metastases in many. Kronlein, in 1905, also encountered this problem and was unable to make an early diagnosis in twenty cases.

The ultimate mortality today is still an appalling one, being placed as high as 90 per cent by some

Figure 1.—Photograph showing a large hypernephroma involving almost the entire kidney except for the lower pole. Note the solidity of the tumor. This type is the common kidney tumor of adults.

Figure 2.—Photograph of a large "embryonic mixed tumor" of the kidney, weighing 9.9 pounds. Note the varied picture due to multiple areas of hemorrhagic extravasation, degeneration and necrosis with multiple cyst formations. The tissue is friable and lacks supporting stroma. This is the common kidney tumor of children.

observers (Braasch). The onset is very insidious. By the time hematuria, pain or tumor appear, the case may be in an advanced stage. Gregoire attempted to apply surgical principles to renal tumor by a radical resection of the primary renal lymph zone at the time of nephrectomy, but, aside from technical difficulties, metastases occur chiefly by way of the blood stream to remote parts of the body, as a glance at the following tables shows quite forcibly.

Distribution of metastases in 176 cases of hypernephroma (Watson and Cunningham):

<i>Hematogenous</i>	Cases
Lungs	26
Bones	35
Internal organs	29
Liver	8
Brain	4
	102
<i>Lymphogenous</i>	Cases
Regional lymph glands	11
Scar	9
Adrenal	2
	22
	Cases
Lower G. U. tract	4
General metastases	6
Miscellaneous	7

Distribution of metastases in 307 cases of "embryonic mixed tumors" in children (Walker, Watson and Cunningham):

<i>Hematogenous</i>	Cases
Liver and lungs	34
Internal organs	16
Opposite kidney	11
Nervous system	1
	62
<i>Lymphogenous</i>	Cases
Retroperitoneal glands	12
Mesenteric glands	6
	18
	Cases
Miscellaneous	7

Metastases to a distant part of the body may lie dormant for a number of years. It has been found that cases have died six years after operation, and Kronlein cites a case which succumbed twelve years later.

The outlook is discouraging. So long as surgery remains the only hope in the face of this appalling mortality, the surgeon must make earlier diagnoses, inasmuch as more radical surgery is useless. The public, as well as physicians, should be thoroughly familiar with these facts, and the urologist should realize his personal responsibility by studying and improving methods of investigation. The urologic study of suspicious cases must be complete, thorough, and prompt in order to increase the percentage of early diagnoses. The findings of ureteral catheterization, pyelography and renal functional studies are not infallible. Even the urologist cannot make an accurate diagnosis in the majority of early cases.

HISTORICAL NOTE

Early descriptions of epithelial tumors of the kidney appear in the writings of König, Rayer, Parker, Shepherd, etc. Robin, in 1855, put forth the first definite description, showing them as being derived from the tubular epithelium. This was accepted by Waldeyer, Klebs, Recklinghausen, etc., who classified kidney tumors as benign adenomas and infiltrating carcinomas. In 1870, Catanni was apparently the first to recognize the occurrence of the sarcomatous elements. The first epochal article to appear was that of Grawitz, in 1883, wherein he recognized the yellowish cortical tumors to whom Birch-Hirschfeld, in 1892, applied the term "hypernephroma." They were regarded as springing from adrenal rests in the kidney. In 1894, the second great group of kidney tumors were described by Birch-Hirschfeld. From their structure, he suggested that they arose from Wolffian body rests and were mixed as to constituent tissues. He named them "embryonic adeno-sarcomata." In a very able discussion appearing in 1899, Wilms furthered the embryonic theory and called them "mischgeschwulste" or mixed tumors.

Since then there have appeared from time to time excellent discussions, but fundamentally very little has been added to the work of original investigators (Beneke, Muus, Sudeck, Klose, Garceau, Busse, Ribbert, Wilson, etc.)

Pathogenesis—The histogenic origin of the large groups of kidney tumors is still in doubt. Grawitz originally, and later Birch-Hirschfeld, showed that the hypernephroma came from adrenal rests in the kidney. This was later contested by Stoerck, who is of the opinion that their origin is renal. Wilson derives them from the nephrogenic blastema, and has applied to them the term “mesothelioma.”

The views regarding the pathogenesis of the “mixed tumors” can be summarized as follows:

- (a) That their origin is due to inclusions of Wolffian body tissue (Birch-Hirschfeld).
- (b) That aberrant cells of the myotome and sclerotome are responsible for the tumor growth, and that the apparent mixed character is to be explained by the varying constituents which enter into the ultimate formation (Wilms).
- (c) That these tumors are derived from the embryonic tissue of the true kidney, which persists and becomes metamorphosed (Busse, Muus, Ewing).

Due to this uncertain knowledge of origin, many classifications have been brought forward. For clinical purposes, the following from Eisendrath is probably the best:

- 1. Primary Neoplasms of the Parenchyma:
 - Epithelial Type:
 - (a) Adenoma.
 - (b) Carcinoma.
 - Connective Tissue Type:
 - (a) Benign—fibroma, myxoma, chondroma, leiomyoma and rhabdomyoma, angioma.
 - (b) Malignant—sarcoma.
 - (c) Embryonal adenomyosarcoma—also called teratomata or mixed-cell tumors.
 - Neoplasms Due to Misplaced Adrenal Rests—Hypernephroma.
- 2. Primary Neoplasms of the Renal Pelvis:
 - Epithelial Type:
 - (a) Papilloma (benign).
 - (b) Papillary carcinoma.
 - (c) Epithelioma (squamous-celled).

CLINICAL

Incidence—Renal tumor is not a very common occurrence. Collected statistics show that in general they occur in adults from 0.06 to 0.1 per cent.* In the University of California Hospital, from 1906 to 1923, inclusive, there have been twenty-nine cases among 46,800 admissions—0.06 per cent. In adults their relative occurrence among tumors in general is from 0.5 to 2 per cent; in children, they constitute about one-fifth (20.4 per cent).*

From the confusion as to pathogenesis and types, the hypernephromata and embryonic mixed tumors are the two most frequently found. The former occurs most frequently during late adult life, and the latter during early childhood. Next in frequency are the carcinomata of the parenchyma, papillary carcinomata of the renal pelvis and squamous-celled carcinomata of the renal pelvis.

* Hinman & Kutzmann: Malignant Tumors of the Kidney in Children. Ann. Surg., 1924, lxxx, 569.

Figure 3.—Chart showing age incidence of hypernephromata and “embryonic mixed tumors.” Note that the hypernephromata occur chiefly in old age, and “mixed tumors” in childhood. Based on 267 hypernephromata and 341 “mixed tumors.”

Diagnosis—The signs and symptoms are an important factor in diagnosis, and yet they may not be pathognomonic. We are often confronted with a paradox; we must try to cure tumors which run a rapid and fatal course unless an early diagnosis can be made, and yet their onset usually is insidious; and when they present themselves with the usual diagnostic group of symptoms, the case may be beyond help, in spite of the fact that no metastases are clinically demonstrable. There present themselves a group of symptoms which have been found to be more or less constant, namely, the “cardinal trio”—hematuria, pain, and tumor. It has been our experience that when a case presents these symptoms, the diagnosis is not an early one and the case usually terminates fatally, in spite of surgical aid, and yet over one-third of cases coming to operation present these symptoms. To add to the difficulty it has been found that the pre-operative duration may be no index of the prognosis. Cases may even terminate fatally and never at any time show any sign or symptom. The lesson to be learned is that the appearance of any single symptom should at once lead to a thorough investigation.

The following table, prepared from various sources (Willan, Barney, Israel, Squier, Albrecht) presents at a glance the prevalence of the signs and symptoms in adults:

SIGNS AND SYMPTOMS OF MALIGNANT TUMOR OF THE KIDNEY IN ADULTS		
	Initial Per cent	Associated Per cent
Hematuria	21.4-70 Av. 42	80
Pain	30-40 Av. 35	58
Tumor	18-20 Av. 19	85
Weakness and loss of weight (cachexia)	9-20 Av. 13.5	75
Varicocele (left)	15
Fever	8
Anorexia, vomiting, edema of legs, metastases	Rare	...

In children, the problem is even more difficult. Added to the insidiousness of onset, tumor is usually

Figure 4.—Typical pyelogram of a malignant tumor of the kidney (hypernephroma) showing the "spider leg" deformity.

Figure 6.—Photograph of pyelogram of a polycystic kidney. The filling defects in these cases often simulate a malignant tumor and must be carefully differentiated.

the initial symptom; also, the protuberant abdomen of young children tend to mask this sign. Such tumors usually are not found until they have attained a large size, by accidental palpation or after cachexia and weakness have set in. The following table shows the prevalence of the signs and symptoms in children:

SIGNS AND SYMPTOMS OF MALIGNANT TUMOR OF THE KIDNEY IN CHILDREN		
	Initial Per cent	Associated Per cent
Tumor	42-71 Av. 57	90
Pain	7-20 Av. 14	20
General weakness	11	
Vomiting	8.8	
Icterus	2.2	
Diarrhea, constipation, ascites	1 ea.	
Hematuria	Rare	5-35 Av. 14

That we have failed to make but little impression on the prognosis, is shown by the fact that the morbidity still ranges about the appalling figure of 90 per cent. We must be open-minded in facing this tremendous problem. Such a high figure in the ultimate mortality shows that diagnosis is too long delayed, either because the urologist is not seeing hematuria cases early enough, or because his methods are yet inadequate to make an early diagnosis. The important significance of blood in the urine must be taught, even though it be the only symptom and transient. Fraser reports a case of renal tumor in a child where there was a transient hematuria one year before operation, and yet the case was not seen by the surgeon until the tumor had reached a large size. Obviously, the urologic surgeon cannot be asked to cure malignant tumor if the case has gone until metastases have probably taken place.

Our experience with malignant tumors of the kidney is far from cheerful, yet it is probably no dif-

ferent from that of many others. In the last eighteen years, twenty-nine cases have presented themselves for treatment. Of these, twenty-three cases were definitely proven, while the remaining six have insufficient data. Seventeen cases occurred in adults, and six in children. Of these, eleven were operated upon; ten either refused operation or were deemed inoperable; two were completely missed during life and found at autopsy. But two cases are alive of the surgical cases and of these, one was lost sight of two months post-operative; the remaining case is still living and well seven months post-operative, so that we have no cases coming within the period of cure. The remaining surgical cases succumbed in from several days to two years. We can, therefore, expect practically a 100 per cent morbidity.

It seems that most of these cases were seen in the late stages of the disease. The following table, briefly shows their occurrence as to initial symptomatology:

Hematuria	} 8 cases
Pain		
Tumor		
Hematuria or Pain or Both	} 6 cases
Tumor	(all children)	5 cases
Cachexia and weakness		1 case
No urologic symptoms		3 cases
Aortic aneurysm		1
Pulsating tumor of skull		1
Exophthalmos		1
		23 cases

Note that eight cases showed all three signs and symptoms, that five cases had large abdominal tumors, and one with cachexia—fourteen cases (60 per cent) in which at once the prognosis was a bad one. Twelve cases showed no clinical metastases,

and of these ten were operated. Eleven cases showed clinical evidence of metastases, and of these one was operated upon. This was a case which entered with a pulsating tumor of the right parietal bone, due to a head injury six weeks previously. The tumor was removed, and upon pathological examination proved to be a hypernephroma metastasis. Careful re-examination of the patient revealed a tumor of the left kidney which had been missed upon the first examination. Urological examination confirmed the diagnosis of left kidney tumor. The patient was again subjected to a most rigid physical examination, but no further evidence of metastases were found. In view of the fact that there are several reports of cases in the literature living and well over six years in whom a solitary metastasis was removed with the primary kidney tumor, a nephrectomy was performed. This patient is living seven months post-operative, without any further signs of metastases and has gained twenty pounds in weight.

Several of the cases have brought forth interesting points and difficulties as to diagnosis. One case entered the hospital with a large pulsating aortic aneurysm. This ruptured and caused death. Autopsy revealed a hypernephroma of the left kidney, yet at no time had there been any signs nor symptoms referable to the urinary tract. A similar case

Figure 5.—Drawings showing pelvic deformities of "mixed tumors" of the kidney in children, as demonstrated by pyelography.

entered the hospital with a slight hematuria. Examination revealed a strongly positive Wassermann and widely dilated aortic arch. Urologic examination revealed only a slight deformity of one of the pelves suggesting tumor. In view of the other findings, the kidney condition was considered luetic. The patient died one year later, and autopsy revealed a hypernephroma with metastases to the liver.

A third case entered with a severe hematuria of several days' duration. The history showed that there had been a transient attack of diplopia ten months previously associated with a glycosuria. The glycosuria was still present with the hematuria. The case was considered inoperable, and the opinion was that there might be pancreatic and cerebral metastases.

Two cases in children, one with an exophthalmos and the other with a swelling to the side of one eye, were seen. Post-mortem examination of each revealed a neurocytoma with intracranial metastases. A third case in a child did not present itself for treatment until the tumor had reached huge proportions, weighing ten pounds.

The urologist must be ever on the alert for pitfalls. If any impression is to be made on the prognosis of malignant kidneys, the case must be seen

early. Careful attention must be paid to any individual sign or symptoms as they appear. The urologic examination should be complete and thorough, including ureteral catheterization, functional and urinary studies and careful pyelographic studies. Hematuria is the most important leading symptom. Its presence nearly always means an organic lesion in the urinary tract and should never be considered lightly or without significance, even though it be transient. Patients should be encouraged to seek advice from the surgeon as early as possible, for in doing so, not only will the opportunity for cure of renal tumor be enhanced, but also other conditions producing similar signs. Thus, Kretschmer found, in an analysis of 200 cases of hematuria, that 43 per cent were due to new growths in the urinary tract.

SUMMARY

1. The incidence of malignant tumors of the kidney are to the extent of 0.25 to 1 per cent in adults; 0.06 to 0.1 per cent in children. Of tumors in general, they constitute from 0.5 to 2 per cent in adults, and about 20 per cent in children.

2. The pathogenesis of kidney tumors is still in the hypothetical stage. The types most commonly found are the hypernephroma, occurring chiefly in late adult life, and "embryonic mixed tumors" found during early childhood.

3. Clinically, all renal tumors should be considered malignant because of the great rarity of the benign types.

4. The classical signs of kidney tumor are hematuria, pain, and tumor. Hematuria is the most frequent initial symptom in adults, while tumor is in children.

5. The importance of each symptom should be considered initially as it appears, and the diagnosis not allowed to wait until the clinical picture is complete.

6. Only by thorough early investigation can we hope to influence the present appalling morbidity of 90 per cent.

7. The urological examination should always be complete and include a differential examination of the urine, functional studies, and ureteropyelography.

8. The correlation of the clinical findings and urological findings should be carefully entered into so that a diagnosis may be arrived at in the doubtful cases.

380 Post Street.

DISCUSSION

GEORGE F. SCHENCK, M. D. (Westlake Professional Building, Los Angeles) — Drs. Hinman and Kutzmann are to be congratulated on the straightforward and concise presentation of their subject. It is to be noted that they are lamenting over the fact that their cases were not seen early. Hematuria is the outstanding symptom of malignant tumors of the kidney.

Hematuria is a symptom that is perhaps the most constant and significant symptom in genito-urinary diseases. It may occur in nephritis, pyelitis, hydronephrosis, polycystic kidneys; kidney, ureteral, and bladder stones; tumors of the kidney, ureter, bladder, and urethra; ulcers of the bladder; adenoma of the prostate; carcinoma of the prostate; prostatitis, vesiculitis, stricture of the urethra, renal

tuberculosis, malaria, and several drug intoxications. It is a symptom that is due to a definite pathological condition that can be definitely determined in a large majority of the cases.

Unfortunately, the trend of all genito-urinary diseases is progressive. The vast majority of hematuria cases are given some internal medication and told to report in three or four days. Unfortunately, many cases of hematuria will subside spontaneously and not reoccur for months. In the meantime, much valuable time is being sacrificed, and the disease is progressing rapidly. In fact, nothing short of marked and persistent hematuria will get the patient a thorough examination, and if indicated, cystoscopy, kidney study, and pyelo-uretero-grams.

Personally I think if physicians would pay more personal attention to voided specimens of urine and do microscopical examinations of routine urine, they would discover hematuria cases earlier than heretofore.

A word about therapy in the malignant tumors of the kidney: Dr. Keyes makes a wide exposure by extending the usual oblique incision well forward, and, if need be, to divide the anterior sheath of the rectus muscle transversely. Then he does an extra-capsular nephrectomy. His reasons are it may delay metastases, there will be less oozing, less chance for infection, and a better opportunity to heal the incision by primary union.

Dr. Barringer thinks hypernephromas are hopeless for radium packs or deep x-ray therapy.

NATHAN G. HALE, M. D. (Capital National Bank Building, Sacramento) — The urological section is to be congratulated that this subject has been presented to us so clearly by those whose experience well fits them for the task.

Renal tumors are, in most instances, neglected because one of the first symptoms, hematuria, is treated expectantly. There could not be a better warning than blood in the urine, yet it is surprising to note the number of cases where blood in the urine sends the patient to the doctor, and the doctor treats this characteristic symptom lightly.

The urologist's difficulties in diagnosing an early tumor are great. The pyeloureterograms are not characteristic in many of the early cases, and, for that reason, pyeloureterograms, at intervals, should be insisted upon by the urologist when the diagnosis is not conclusive.

In operating, the so-called cardinal principle of removing the perirenal fat in toto with the kidney tumor, on account of possible invasion of this fat by the cancer, is the only procedure in renal surgery for malignant tumors that has been suggested as an improvement in technique for a number of years; and this is of little avail on account of the many cases that metastasize by way of the blood stream.

In conclusion, I hope that the stimulus of this excellent paper will start investigation concerning malignant renal tumors, which will result in an earlier diagnosis and a better surgical attempt at complete removal.

PAUL A. FERRIER, M. D. (Citizens Bank Building, Pasadena, Calif.) — Doctors Hinman and Kutzmann have made the thorough study that we have learned to expect of them. The conclusion cannot be escaped that present surgical methods in malignant tumors of the kidney are well-nigh futile—at best a short reprieve. It is a service to dissuade from unwarranted surgery. The problem awaits solution with that of deep-seated malignancies elsewhere.

DOCTOR HINMAN (closing) — In conclusion, I should like to emphasize the great importance of hematuria as an early symptom of renal tumor, and that this hematuria need not always be macroscopic before recognition. If physicians would acquire the habit of routine examination of urine, by having the patient void in three glasses and examining the second glass for evidence of disturbance in the bladder or above, much more definite findings would be possible. Microscopic study of such urine showing R. B. C. would be evidence of pathology, even though there would not be pronounced bleeding.

The writers appreciate the excellent discussions of their paper that have been given.

DOUBTFUL TUMORS—SHALL WE EXCISE A PIECE FOR DIAGNOSIS?

By A. R. KILGORE, M. D., San Francisco

In essence, this paper is a plea, not against diagnostic incision of tumors, but against delay between such incision and complete operation.

IF WE take out an appendix when the real trouble is a kidney stone, we can correct ourselves another day and still cure the patient. But if we leave live cancer cells in a patient and cause, by our interference or permit by our delay, metastasis to take place, we have lost the only chance we had of obtaining a cure. Cancer, of all diseases, must be treated right the first time.

Excision of a piece of tissue for diagnosis offers the most accurate method of diagnosis available, but under varying conditions it may or may not cause metastasis to take place. When it is safe, we ought to be prepared to use this method; when it is unsafe, we ought by all means to avoid it.

Excision of a piece of tissue or of an entire small growth for diagnosis has had ardent support and just as ardent condemnation. When the Harvard Cancer Commission and the New York Board of Health proposed the establishment of free tissue diagnostic services, a storm of criticism was aroused. Dr. Greenough, of the Harvard Cancer Commission, addressed a questionnaire to the members of the American Surgical and American Gynecological Associations to determine prevailing opinion. He found extraordinary disagreement among the men of widest experience in this country, and there is still anything but clear-cut opinion on the part of surgeons generally.

If there are definite facts available from which to draw definite conclusions, those facts ought to be generally recognized and our procedures standardized accordingly.

ANIMAL EXPERIMENTATION

Animal experimentation has not been of great help because the behavior of animal tumors in the matter of metastasis does not parallel that of human tumors closely enough to make it safe to accept experimental evidence in its entirety as applying to human neoplasms. There have been three outstanding communications, however, bearing directly or indirectly on the point in question. F. C. Wood found that aseptic incision of a transplanted sub-cutaneous tumor in rats did not materially increase the number of metastases, as demonstrated at autopsy several weeks later. He was working, however, with an adeno-carcinoma—the so-called Flexner-Jobling tumor—the histology of which is certainly not closely akin to that of human scirrhous or squamous cell cancers.

On the other hand, both Tyzzer and Knox have shown that a very small amount of gentle massage of various animal tumors enormously increases metastasis, and the latter author has shown that the amount of increase in metastasis produced by massage varies directly with the cellular malignancy of the tumor. Neither of these authors experimented with excision of a piece of tumor tissue, but the amount of massage (one to two and a half minutes) described in their experiments is probably not greater than the manipulation necessarily incident to the

operation of excision of a piece of sub-cutaneous tumor.

Incidentally, these papers bring home one very important clinical lesson—the importance of gentleness in the palpation of tumors for diagnosis. If one or two minutes of gentle massage will enormously increase the metastasis of a tumor, what must happen to a breast cancer palpated extensively by several consultants and a group of medical students. One gentle application of the fingers is sufficient to determine the presence of a lump, and if the fingers are trained, the same single palpation is enough to determine size, shape, and consistency of the lump and the presence or absence of fixation to the skin or deep structures. Here, certainly, is one condition in which it is better to sacrifice painstaking and complete description of the characteristics of the lump in the interests of safety to the patient. We cannot help what the patient has already done by feeling or rubbing the lump, but we can avoid the catastrophe of further spreading metastasis by our own diagnostic procedures.

If, then, animal experimental evidence is inconclusive, are there definite facts available upon which to base opinion for human tumors?

It is first absolutely essential to recognize that human tumors behave in widely different ways, varying with the cell type and with the location in the body. The question is not, can we safely excise a piece of a doubtful human tumor, but can we safely excise a piece of a scirrhus breast tumor; can we safely excise a piece or the whole of a squamous cell lip growth, etc. It is the purpose of this paper to discuss individually the commoner tumors for which we should standardize our procedures in the matter of excision for diagnosis.

1. THE BREAST

Very definite facts are available in the case of the breast. Bloodgood has analyzed the end-results in eighty-nine cases of breast cancer so early that the clinical diagnosis was "benign." Twenty of these were approached by excision of the tumor mass. Some days later, after microscopic study, excision of the breast and axillary contents was done. *All of these twenty were dead within five years.* In fifteen, the entire breast was first removed and later, after microscopic study, the axillary dissection was done. Two of these, both having early adeno-carcinomas, remained well after five years—less than 7 per cent cured. Fifty-four cases were approached by exploration, the diagnosis made on the operating-table by gross appearance or frozen section, and immediate complete breast amputation and axillary dissection performed. Forty-three cases were well after five years—80 per cent cures.

In the face of such definite, known end-results, theoretical discussion has no place. Exploratory incision is safe, but only if immediate complete operation follows. Delay for laboratory diagnosis (except by immediate frozen section) destroys nearly all chance of cure.

The mechanism of metastasis in breast cancer offers some explanation of these facts. Handley has shown by a beautiful piece of research that cancer of the breast tends to metastasize, not only by embolism

of separate fragments of cancer carried by the lymphatic stream, but also and very commonly by actual continuous growth along the lymphatic vessels, so that a solid cord of cancer may extend from the breast tumor to the axillary nodes. If, therefore, the tumor is excised, or even the breast amputated, microscopic strands of cancer may be cut across with the knife, implantation in the wound may occur and also stimulation by the injury of the cancer cells in the cut lymphatics to more rapid growth and spread.

Why, then, are many surgeons confident, from their own experience, that they have cured breast cancer by two-stage operations? There are two obvious reasons: 1. Failure to recognize the difference in behavior of different types of breast cancer. Certain adeno-carcinomas, when pure and not mixed with true scirrhus or medullary cancer, metastasize late or not at all. If the surgeon removes a breast containing such an adeno-carcinoma and receives from his pathologist a diagnosis of "cancer" and then later performs an axillary dissection, his patient will remain well. She might have remained well without the axillary dissection because no metastasis had occurred, but she is set down in his records as a case of "breast cancer" cured by a two-stage operation.

2. Mistakes in pathological diagnosis. Some pathologists who do not see patients clinically and follow them tend to make histological diagnoses of "cancer" on microscopic cell appearances that are borderline or, at most, not typical scirrhus or medullary cancer. Or they are actually incompetent and call blood-vessels in granulation tissue cancer. I have actually seen this done and axillary dissection later performed on such a diagnosis. Such "cancers" are "cured." They would have been cured if the axilla had been treated by an electronic machine or a cancer paste. No cancer is there. Our statistics of operative cures of cancer of the breast will be worthless until we distinguish sharply between true scirrhus or medullary cancer and the adeno-carcinomas and borderline or doubtful or actually mistaken histological pictures.

2. THE LIP

Here again, definite facts are available. Both Bloodgood and Broders have published extensive end-result studies. The former states that, in his experience, where a correct V-excision has been made, no case has ever had a local recurrence. The primary tumor has been studied in the laboratory as a routine, and if more than "transitional stage" malignancy is present, a neck dissection is subsequently done. One hundred per cent have been cured when no neck glands could be demonstrated pathologically to have metastasized, and 50 to 70 per cent have been cured even when metastasis has been found.

A two-stage operation is, therefore, safe in the case of the lip. This fact is also readily explainable, for squamous cell carcinomas of the lip apparently metastasize chiefly by embolism and not by continuous lymphatic permeation as in the case of the breast, so that excision of a lip growth through surrounding healthy tissue cuts across no strands of cancer in lymphatic vessels. A preliminary excision of the primary growth is of tremendous advantage, because

in the early stages of malignancy, as demonstrated by the microscope, neck dissection is unnecessary, since no metastases have yet taken place.

Is it justifiable to excise a piece instead of the entire primary growth? Why do it? The large growths are obvious clinically. Small lesions are easily excised without deformity resulting, and excision leaves no remaining lesion to act as a precancerous focus.

3. THE SKIN

Considerations for skin lesions are identical for practical purposes with those for the lip. In the case of large lesions situated so that excision would be mutilating, and where diagnosis cannot be made clinically, excision of a piece of the growing edge may be justified, but these cases are rare.

4. THE TONGUE

Here the situation is different because the chances of operative cure, except in very early growths, is remote. Less than 10 per cent of tongue cancers can be cured surgically, while removal of any but small growths involves distressing mutilation. When diagnosis cannot be made clinically, excision of a piece is without doubt justifiable.

But here again, if only a piece of a syphilitic or other ulcer of the tongue is excised the remainder of the ulcer is potentially precancerous. This fact is forcibly illustrated by a record in my possession of a case of small syphilitic ulcer of the tongue, incised for diagnosis, which became fully developed cancer within two months. When a tongue lesion can be excised completely without mutilation, this should be done.

5. THE UTERUS

Among the replies to Greenough's questionnaire, previously mentioned, there was widest diversity of opinion about the removal of tissue from the cervix or the curetage of the fundus for the diagnosis of cancer. In a recent personal communication, Dr. Greenough states that the disagreement is just as pronounced today. His own opinion, based on his experience in his clinic and at the Huntington Hospital, is expressed thus: "While I fully believe that a biopsy should be avoided in every case where a diagnosis can otherwise be made, I fully believe also that a biopsy is to be preferred to delay in awaiting positive symptoms by which the diagnosis can be made. . . . We have practiced biopsy on all our radium cervix cases at the Huntington as a routine, and we have not been able to establish the fact that the biopsy in any way diminished the prospect of cure."

Dr. Thomas Cullen of Johns Hopkins also kindly complied with a request for a statement of his opinion and practice. I quote from his illuminating comments: "We do not want to cut into malignant tumors if we can avoid it, and when removing a surface growth . . . cut around it, but if the surgeon refuses to cut into a suspicious cervix, what will he do? Will he watch the patient week after week, losing valuable time in the occasional case of malignancy, or will he go ahead boldly and remove the uterus in all suspicious cases, thereby doing many unnecessary hysterectomies. How is he going to re-

lieve the many cases of uterine hemorrhage unless he knows just what the patient's bleeding is due to? Personally, I take little or no stock in the view that removal of a small wedge of the cervix is fraught with any danger of spreading cancer if it exists. The cervical tissue is very dense and does not lend itself readily to the escape of cancer cells into the parametrium and further, even if there were danger, I would rather take this than subject the patient to an unnecessary hysterectomy where no malignancy exists.

"From two-thirds to three-fourths of the cases of cancer of the body of the uterus, if operated on fairly early, remain well. Nearly all of these have been diagnosed from scrapings. In former days the hysterectomy was performed several days after the removal of the wedge from the cervix or after curetage—now it is commenced within ten to fifteen minutes—just as soon as the frozen section is diagnosed."

I want to call special attention to the last statement. In one of the largest and best gynecological clinics in America, it is felt that recourse must be had to microscopical examination in the diagnosis of early cervix and fundus cancer; yet, while many cases have been cured by a two-stage procedure, it is the practice now to "play safe," make the diagnosis from frozen section and perform the operation for cancer, if present, at the same sitting.

6. SARCOMA

Small, excisable sarcomata should obviously be completely removed. Nothing is to be gained by preliminary section. In large, connective tissue tumors the question is usually one of avoiding unnecessary operation. If we realize that mutilating operation—amputation, etc.—is useless for malignant sarcoma and unnecessary for benign connective tissue tumors, the advantages of microscopic diagnosis are obvious, but here again, frozen section is the method of choice because some benign tumors (e. g., the myxoma of bone) implant and metastasize if left in place after being cut into.

SUMMARY

In essence, this paper is a plea, not against diagnostic incision of tumors, but against delay between such incision and complete operation. In at least one situation (the breast) the two-stage procedure has been proven to destroy almost all chances of cure in the more malignant forms of cancer. In other locations (the uterus and cervix) the evidence is not so convincing as to absolutely condemn curetage or removal of a piece of tissue and delay for laboratory diagnosis, but the ideal procedure is frozen section diagnosis and immediate complete operation when this gives positive evidence of the presence of cancer.

In the case of the lip, removal of the primary growth complete (rather than incision of the growth) is a safe procedure with dissection of the neck lymphatics at a later time, depending on the microscopic appearance of the primary growth.

For lesions of the skin and of the tongue the same procedure is to be recommended as for those of the lip, except that in large growths of the tongue, where complete excision would be seriously mutilating and the chances of curing cancer remote, diagnostic in-

cision seems justifiable when the lesion cannot otherwise be accurately identified.

Small connective tissue tumors should be removed intact—certain large ones explored for gross appearance or frozen section diagnosis.

HIGH PROTEIN RATION AS A CAUSE OF NEPHRITIS *

By NEWTON EVANS, M. D., AND E. H. RISLEY, M. D.,
Loma Linda, Calif.

(From the Departments of Biochemistry and Pathology of the College of Medical Evangelists)

Review of selected literature.

Experiments recorded.

It is evident that, to be technically correct in view of present knowledge and ideas, the term "parenchymatous nephritis" should be quite largely avoided.

Animals fed on the high protein ration for prolonged periods showed nephritic changes, without exception.

We believe that the results of these experiments substantiate the correctness of the low protein ration as one of the important measures in the prophylaxis and therapy of nephritis.

DISCUSSION by T. Addis, San Francisco; Eugene S. Kilgore, San Francisco.

NO CONSIDERATION of the causes of nephritis can be satisfactory without including recognition of the classification of these conditions. Obviously, a classification may be attempted upon one of several different bases: anatomical, histopathological, clinical or etiological, or a combination of these. It is recognized by all that a satisfactory classification must take etiology into account, and since little has been known of the real causes of nephropathies until recent years, the attempts at classification have been numerous but unsatisfactory and confusing. When some of us were medical students twenty-five years ago, the histo-pathological classification presented included the two main divisions, "parenchymatous nephritis" and "interstitial nephritis" with subdivisions. The term "chronic interstitial nephritis" was used to indicate all contracted kidneys, those in which there was a manifest growth of new fibrous tissue. Although the term "chronic interstitial nephritis" still occurs in some textbooks and in the vocabulary of many physicians the present tendency is to eliminate the term from our nomenclature. It is now recognized that any type of true nephritis, if it exists for a sufficiently long period, ultimately eventuates in the fibrous contracted kidney (secondary contracted kidney), whether the original process is a tubular nephritis, a glomerular nephritis or the very rare true interstitial nephritis; or whether it is the slowly progressive process of the arteriosclerotic kidney (primary contracted kidney).

There seems also to be, even now, a lack of uniformity in the use of the term "parenchymatous nephritis," sometimes used as referring to conditions of primary tubular degeneration and by some used to include both those cases in which the primary change is in the tubular epithelium and the more frequent

cases in which the glomeruli are principally involved. It is evident that, to be technically correct in view of present knowledge and ideas, the term "parenchymatous nephritis" should be quite largely avoided.

In the literature of recent years the most quoted authority on the classification of the nephropathies is the monograph in German of Volhard and Fahr, published in 1914. In brief, they recognize:

1. The nephroses—degenerative lesions of the tubular epithelium.

2. The true nephritides—glomerular nephritis—inflammatory lesions primarily in the glomeruli.

3. The scleroses—contracted kidney due to arteriosclerosis of the renal arterioles.

In the first group (the nephroses), with tubular degenerations they recognize an acute course, a chronic course and a final stage with fibrous contracted kidney (one form of secondary contracted kidney).

In the second group (true glomerulonephritis), there are two sub-classes: First, the diffuse form (the more usual), and second, a focal form, each of which may be seen in three stages, all ending in a contracted kidney (secondary contracted kidney).

In the arteriosclerotic kidney (primary contracted kidney) the scleroses group, they divide the cases into benign hypertension cases and malignant hypertension cases, the latter being, according to their view, a combined form of arteriosclerotic contracted kidney and true nephritis.

Notwithstanding the general tendency to follow quite faithfully this classification of Volhard and Fahr, it is evident that from a strictly clinical standpoint it is frequently not possible thus to classify actual cases accurately. The majority of clinical observers are satisfied to characterize the conditions as (1) acute, (2) subacute, or (3) chronic nephritis, or as a (4) chronic arteriosclerotic or vascular nephritis, not attempting to differentiate clinically between tubular and glomerular nephritis. Such a classification is followed by Newburgh in his recent extensive paper on the etiology of nephritis in "Medicine."

Henry A. Christian presents a practically identical division except that he recognizes the possibility of dividing all *chronic* cases into three groups: the true chronic nephritis, the arteriosclerotic cases, and a combined group, meaning an arteriosclerotic kidney in which the true chronic nephritis process is associated.

ETIOLOGY

The one important etiological factor in true nephritis now accepted by all observers is that of infections, principally the streptococcus infection. As presented clearly by MacCallum, the more intense acute infections, such as general peritonitis and acute septicemias, usually produce tubular changes, while the less severe types of infections, especially the subacute forms, such as those produced by the non-hemolytic streptococci, are associated with glomerulonephritis, including acute, subacute and chronic forms. Acute tubular epithelial degenerations, as is well known, are also caused by various mineral poisons and other toxic substances. The type of these is the kidney of bichloride of mercury

* Read before the County Medical Society, Los Angeles, Calif., January 3, 1924.

poisoning. In toxemias of pregnancy and in eclampsia, there are typical tubular degenerations.

The first to elucidate in a comprehensive manner the important relationship of streptococcic infections to acute and subacute glomerulonephritis was Löhlein, in 1907. His careful pathological and clinical observations have been generally accepted and confirmed by many workers, from both an experimental and clinical standpoint. Probably the streptococcic lesions which give rise to the greatest number of recognized nephritides are those of the tonsils. Among others, Ophüls has published a number of reports of clinical and autopsy studies on nephritis (1912 and onward), showing the importance of streptococcus infection in the causation of nephritis.

In recent years attention has been called to an entirely different group of causes of nephritis. W. T. Longcope, in 1913, reported remarkable anatomical changes in the liver, myocardium and kidneys, following anaphylactic shock from foreign proteins injected in experimental animals. Later, in 1915, he reported other experiments, showing that similar necrotic and inflammatory changes (though less intense) occurred in the kidneys as well as heart and liver, from the parenteral injection of large doses of foreign proteins in animals not sensitized and in which no anaphylactic reactions occurred. Evidently, the foreign protein in sufficiently large doses exerted a toxic destructive influence upon the kidney tissue; but we should not overlook the fact that in these experiments the protein material was introduced directly and was not ingested as a food.

In 1919, Newburgh conceived the idea that possibly the products of nitrogenous metabolism, which normally do not injure the kidney, are capable of producing serious damage if the kidney is called upon to eliminate them in excessively large amounts. This conception was based upon the fact that, although the normal kidney is capable of secreting such toxic mineral salts as mercuric chloride in small amounts, the tubular epithelium suffers severely if it is called upon to handle this poison in stronger dilution. He accordingly undertook to ascertain the effects upon the kidneys of rabbits, of feeding excessive amounts of protein food. In several series of experiments he used different proteins: egg-whites, soy beans, and

SUMMARY OF RAT-FEEDING EXPERIMENTS
High Protein Diets

Diet	No of Rats	Growth	Albumin in Urine	Per cent showing definite Microscopic Pathology	
				Tubules	Glomeruli
Controls ordinary diet	10	Good	(No. tested, 9) Pct. positive, 11 trace only	0	0
Casein	4	Poor	(No. tested, 0)	100	25
Casein and wheat gluten	4	Fairly good	(No. tested, 3) Pct. positive, 100	75	75
Meat	6	Good	(No. tested, 2) Pct. positive, 100	83	33
Nut meal	15	Poor	(No. tested, 2) Pct. positive, 100	47	33
Peanuts	4	Fair	(No. tested, 1) Pct. positive, 100	75	25
Soy beans	5	Fair	(No. tested, 1) Pct. positive, 0	80	60
Wheat gluten	8	Poor	(No. tested, 6) Pct. positive, 100	25	75

TOP
Ordinary Diet.—Normal kidney.

CENTER
Wheat Gluten Diet.—Partially hyalinized glomerulus.

BOTTOM
Meat Diet.—Exudate in Bowman's capsule. Extensive tubular degeneration.

Casein and Wheat Gluten Diet.—Round cell infiltration, fibrous and epithelial hyperplasia of Bowman's capsule.

Casein and Wheat Gluten Diet.—Changes similar to photograph above, but with exudate in Bowman's capsule and adhesion of glomerulus to capsule.

RAT-FEEDING EXPERIMENTS, HIGH PROTEIN DIET (WHEAT GLUTEN)						
Number	Diet	Months on Diet	Weight Grams	Urine	Pathology	
					Tubules	Glomeruli
54	Wheat gluten	6	34-154	Not tested	Slight pyknosis	Badly diseased. Hyaline degeneration
33	Wheat gluten	9	64-165	Not tested	Normal	Normal
55	Wheat gluten	14	55-197	Albumin +	Some degeneration with pyknosis	Exudate with definite changes
56	Wheat gluten	14	32-111	Albumin +	Moderate pyknosis	Some adherent. Some with exudate
57	Wheat gluten	14	47-160	Albumin +	Some pyknosis	Some thickened and fibrous
58	Wheat gluten	15	61-164	Albumin +	Normal	Moderate changes. Thrombi in capillaries
59	Wheat gluten	15	32-105	Albumin +	Normal	Exudate and epithelial proliferation in a few
60	Wheat gluten	15	62-168	Albumin +	Normal	Small exudate in a few

RAT-FEEDING EXPERIMENTS, HIGH PROTEIN DIET (CASEIN AND WHEAT GLUTEN)							
No.	Diet	Months on Diet	Weight Grams	Urine	Pathology		
					Tubules	Glomeruli	Other Findings
39	Casein and wheat gluten	7	60-239	Albumin +	Some contain casts	Many seriously damaged. Much exudate	
41	Casein and wheat gluten	7	83-172	Albumin 0	Normal	Some contain exudate

43	Casein and wheat gluten	7	94-200	Albumin +	Advanced degeneration. Hypertrophied. Contain casts	Enlarged and many fibrous	Much new formed fibrous tissue

casein. He found that when the animals were killed and the kidneys examined, constant evidences of renal injury were found after feeding excessive amounts of these proteins. Apparently, the soy beans and the egg-whites produced greater injury than the casein. Fifteen grams of casein daily in the average-sized rabbit produced no injury, while 30 grams constantly produced lesions. He was able to recognize nephritis in all stages—acute, subacute, and chronic—ending in typical secondary contracted kidney. The urines contained albumin and casts, and

the blood chemistry determinations showed a constant retention of non-protein nitrogen.

In an effort to determine the specific substances responsible for the nephritis lesions, he made tests which proved conclusively that urea in the amounts present in the experimental animals was not the substance at fault.

These facts reported by Newburgh suggested the desirability of confirming his findings, but it seemed to us that rats would be more suitable material on account of greater similarity to human beings in

their dietetic habits. We accordingly began at once, 1919, a series of feeding experiments on white rats, which we are reporting at this time.

In the May, 1923, number of the Johns Hopkins Hospital Bulletin, there appeared a report of similar experiments in which rats were used by E. V. McCollum and two of his associates. Their experiments were also suggested by the report of Newburgh's work. In beginning their experiments they were impressed by the idea that in Newburgh's rabbit-feeding experiments it appeared that the diets of the animals were abnormal in other features besides being high in protein; for instance, these diets were evidently deficient in essential mineral salts and probably in vitamins. Accordingly, their experimental diets were carefully planned so as to give the rats a well-balanced diet, except in the one feature of abnormally high protein content (31-41.3 per cent). The excessive protein in their mixture was attained by adding various quantities of casein, liver and legumes to other natural food substances. Their final results proved to be in entire accord with those of Newburgh, as indicated by the following quotation: "Notwithstanding the fact that the rats apparently did so well on these diets, they showed kidney damage, without exception. . . . There is apparently no cause other than the excretion of excessive amounts of the end products of protein metabolism to which we can ascribe this renal damage."

These observers also agree with the statements of Newburgh that the histological kidney changes are primarily those of the tubules rather than of the glomeruli.

In the reports of these rat-feeding experiments at Johns Hopkins, there is no indication of any urinary examination of the experimental rats. In Newburgh's rabbit experiments, both albumin and casts were reported. Certain blood chemistry observations, however, are reported in the rat experiments.

In Newburgh's most recent article, he describes several series of experiments on human subjects, both normal and nephritics, which show definite injurious results upon the kidneys following the ingestion of excessive amounts of protein in the form of meat. He also argues from known facts regarding the relative infrequency of nephritis in racial groups habitually living upon a low protein dietary that such a diet is less taxing to the kidney parenchyma than the high protein dietary.

EXPERIMENTS

As mentioned above, in 1919, immediately following the reports made by Newburgh, we undertook feeding experiments with some foods that seemed to be suited for the purpose. Our work has continued more or less steadily from that time to the present and, although covering only about sixty animals, yet it seems to be of enough interest to report. White rats were chosen as the best suited animals, since they are omnivorous, are comparatively easy to care for, they live well in captivity, and have a rather short span of life. This last point makes it possible to follow the test long enough to be comparable to man, and yet not consume too large an amount of time in getting the results.

The animals were kept two in a cage, but no

effort was made to follow successive generations. Care was taken to keep everything in as favorable a condition as possible, so that other influences, aside from the diet, would be practically nil. The animals were weighed and checked up from time to time and account made of their progress. In spite of all our efforts, some of the animals died in the early part of our work, probably due to the one-sided diet which they were receiving. This accounts for some of the low ages given in our reports, as all rats were autopsied and the kidneys studied carefully, regardless of the time they had been under the dietary restrictions. In about one-half the cases, specimens of urine were collected and tested for albumin qualitatively by such tests as Heller's and acetic acid and potassium ferrocyanide. We regret that this was not done with the entire series, but did not at first see the possible significance of such a procedure, and further thought that it would be a difficult task to collect the urine. Collection and examination of the urinary specimens was later simplified and was followed throughout.

The following data give some idea of the character of the foods used:

1. *Casein*—The commercial product and one made in our own laboratory were used, the per cent of protein ranging near 75 per cent. The product was finely ground and was fed to the animals in that form.

2. *Meat*—The meat used was the flesh of rabbits, as we had a surplus stock of those animals on hand at the time. The meat was not allowed to spoil, but was hung in the cage in small quantities at a time. The protein was estimated as averaging 20 per cent, the fat as 12 per cent, and the other solids at about 2½ per cent, making the total solids 34½ per cent. This would make the protein about 58 per cent of the total solid water-free material, exclusive of the bones which were not eaten in any amount.

3. *Nut Meal*—A peanut product having 55.5 per cent protein. This was also used in the form of a finely ground powder.

4. *Peanuts*—Ordinary shelled peanuts. The samples we used averaged about 27 per cent protein. These were fed to the animals whole.

5. *Soy Beans*—Ordinary product from the store. Averaged 39 per cent protein. Fed to animals whole.

6. *Wheat Gluten*—Made from flour by washing out the starch. The sample used ran 44 per cent protein. Finely ground and fed to animals in this form.

7. *Greens*—Ordinary alfalfa, lettuce, beet-tops, or similar products. Proteins very small in amount. These were fed only in very limited amounts, and were designed to keep the animals going better, so far as vitamins and salts were concerned.

We are aware that there are several imperfections in our technic. Perhaps the most important of these is the fact that our dietaries were not balanced in a way that would give reasonably near complete nutrition. Some of our animals showed definite nutritional disturbances from the lack of vitamins, the lack of which was only in part supplied by the green stuffs used. It is interesting that McCollum and his associates, after very careful checking up the

diet from every viewpoint possible, got very similar results, so far as kidney damage is concerned. The work is not as complete in details as might be desired; for example, the percentage of albumin in the urine might have been estimated, the urine might have been studied for the detection of casts, and the blood chemistry might have been studied, although it is rather difficult to get blood from rats during life without injuring them seriously and thus probably bringing other factors to play on the problem.

A series of ten control rats was used to get information as to what might be expected in the examination of the kidneys of normal animals. These rats were fed upon mixed grains and greens. The grains used were wheat, kaffir corn, and maize, with an average protein percentage of about 10. Varying periods of time were taken so as to give data for various ages. As will be seen by the tables, only one showed albumin in the urine and that only a trace, and none showed microscopic change of any moment in the kidneys. We are, therefore, justified in concluding that rats living upon an ordinary diet for periods of sixteen months or less are practically free from kidney lesions.

In studying the animals fed upon the special diets, it is of interest to compare the relative frequency of tubular lesions and glomerular lesions. Our summaries show that the tubules of the kidney are more susceptible to the injurious effects of the high protein diet than are the glomeruli. This is well seen when the average per cent of damage is determined for all the groups, the tubules showing 69 per cent; the glomeruli only 46 per cent. By comparing the different groups on the different dietaries, it appears that in the case of wheat gluten the glomeruli are involved more than are the tubules, while in all other cases the reverse is true. The explanation of this is not clear, and whether any significance should be placed upon it is questionable.

Taking the time factor into consideration, as well as the percentage of protein, it appears that the damage to the kidney is in direct proportion to the content of protein in the diet, with the exception that soy beans and peanuts, although less in protein content, have more marked effects than some of those foods much higher in protein. These products were fed in their original form without grinding, and thus were possibly less completely utilized.

Of the different high protein dietaries used, the meat diet appeared to have the most favorable influence upon the growth of the animals—probably because it more nearly approached the ideal diet in presenting the necessary food elements. Further, the rats with meat had as much of the greens as did the others, but in no case was an excess of the green stuffs used. Next to meat, the animals with the combination of wheat gluten and casein made the best growth. Those fed upon casein, nut meal, and wheat gluten alone did poorly and suffered a great deal from malnutrition. In our early work some of the animals died before sufficient time had elapsed to show marked effects upon the kidneys. Later, the addition of small amounts of greens helped to keep the experiments going for longer periods of time.

The most serious lesions in the kidneys were found in the rats fed upon the mixture of casein and wheat

gluten. In two of these animals fed only seven months on the mixture, very advanced and marked lesions were observed in both tubules and glomeruli. Advanced changes were also found in those fed upon nut meal for periods of ten months or longer. In two cases fed on meat ten and eleven months, the changes were marked. In all of these cases there was definite replacement of renal parenchyma by connective tissue.

The accompanying tables make a further detailed discussion of the kidney findings superfluous, and the characteristic histological changes are illustrated by the photographs reproduced herewith.

SUMMARY AND CONCLUSIONS

1. The control animals fed on an ordinary diet for corresponding periods showed no kidney changes.
2. Animals fed on the high protein ration for prolonged periods showed nephritic changes, without exception.
3. We believe that the experiments carried out by Newburgh, McCollum and others, as well as by ourselves, prove definitely that high protein diet is capable of producing true nephritis in the animals used.
4. There is no question but that there are other factors, such as bacteria, bacterial toxins, mineral poisons, and other toxic materials which are basic in the etiology of nephritis, but it seems very possible that the high protein ration generally used by peoples in temperate zones is a definite etiologic factor.
5. We believe that the results of these experiments substantiate the correctness of the low protein ration as one of the important measures in the prophylaxis and therapy of nephritis.
6. Although the experiments herewith reported were extreme applications of the high protein ration, yet, taking into consideration the comparatively short duration of the test, in some cases not over one-seventh of a rat's life, it seems very plausible that 25 to 30 years, corresponding to one-third or one-half of a man's life, of the moderately high protein dietary would produce some of the damage we see today in the cases constantly coming before us.
7. Since meat is the protein food used most abundantly (Sherman says we use 180 pounds per capita in the United States per year), it would seem wise at least to limit its use in the average dietary to one-half the present quantity consumed, and to correspondingly increase the use of fruits and vegetables, which are low in protein and at the same time yield vitamins and salts of great value.

DISCUSSION

T. ADDIS, M. D. (Stanford Medical School, San Francisco)—The paper demonstrates that abnormalities in the structure of the kidneys may be found in rats which have been given a diet which is high in protein. But there seems to be room for considerable doubt as to whether or not these anatomical changes are due to the high percentage of protein in the food or to some other factor or factors associated with the diet.

The question of the effect of high protein diets is, as a matter of fact, very complex, and the work which has been done has given, apparently, contradictory results. Chalmers Watson (Food and Feeding, Appendix, November, 1910) first reported that degeneration of the renal

tubules, as well as various other extra-renal lesions, result from giving much protein to rats, but Drummond, Crowden, and Hill (*Jour. of Physiol.*, 1922, 56, 413) fed rats for 100 days on a diet which contained 83 per cent of casein, and were unable to find any defect in the kidneys. They suggest that Chalmers Watson's results may have been due to vitamin deficiencies. Newburgh's work on rabbits has been referred to by the authors, but it may be noted that the renal lesions he produced bore no resemblance to true nephritis as seen in man, and I have been unable to confirm his findings as to the effect of a large ingestion of meat on the urinary sediment. The lesions found by Polvogt, McCollum, and Simmonds seem to have been of a quite minor nature, and no very definite changes in the chemistry of the blood are reported. Osborne, Mendel, Park, and Darrow (*Proc. of the Soc. of Exper. Biol. and Med.*, 1922-23, 20, 452) found no microscopical evidence of inflammatory or of degenerative changes in the kidneys of rats fed on diets which contained 75 per cent of either casein or meat; and still more recently Osborne and Mendel (*Am. Jour. Physiol.*, 1924, 68, 143) state that there were no pathological changes in the kidneys of rats which had subsisted on pure protein or protein-fat diets, though they did note renal hypertrophy, whereas in Drummond, Crowden, and Hill's experiments the weights of the kidneys of the high protein fed rats were within the normal limits of variation.

The experiments given in this paper by Dr. Evans and Dr. Risley form an interesting but not, I think, a decisive contribution to the subject. In view of the complete disagreement in the results obtained by different investigators, it would seem that the question as to whether a high protein intake produces renal damage is still unanswered.

EUGENE S. KILGORE, M. D. (391 Sutter Street, San Francisco)—The authors have made a valuable contribution, which, together with the reports of Newburgh, McCollum et al., throws strong suspicion on high protein feeding as one cause of nephritis; and Dr. Addis has pointed out reasons for withholding final conclusions on the relation of protein diets to human nephritis. A further reason for conservatism is the universal difficulty in converting the results of animal experiments into conclusions for man. The rat experiments will have added significance, if they can be confirmed with larger series and with some of the experimental difficulties pointed out by the authors overcome. The comparative span of life of the high protein and normally fed rats would be interesting. And finally, in view of the disagreement of some of the investigators on the nature and extent of lesions in high protein fed animals, it would add materially to the weight of future reports if the possibility of subconscious researcher's bias could be eliminated: e. g., if all or at least the pathological examinations could be made and recorded by one who at the time was uninformed as to whether he was examining test animal or control. This is an experimental precaution seldom taken in medicine, but one which, if followed generally, would save our literature from many contradictions.

In favor of the results of these experiments as applied to man, it must be said that the impressions from clinical experience and insurance statistics are in harmony with the idea that diet is of considerable importance in the etiology of kidney, as well as other degenerative changes. The overweight group, who comprise largely the group of overeaters, have a higher incidence of chronic degenerative diseases and a correspondingly shorter life span.

DOCTOR EVANS (closing)—It would seem that the opinion expressed by Doctor Addis in his discussion of the results of these experiments is of some weight, inasmuch as there is apparent discrepancy in the results of similar experiments in the hands of different workers. It is also true that in our diets, in addition to the high protein content, there may have been a comparative deficiency in vitamins and in the mineral salts. On the other hand, I question the accuracy of some of Doctor Addis' interpretation of available information. He states that the kidney lesions in Newburgh's rabbits have no resemblance to true nephritis as seen in man. Newburgh states in his report of 1919 that the rabbits developed acute, subacute, and chronic nephritis; and it is my impression that the photo-

micrographs which he presents exhibit lesions which histologically bear considerable resemblance to the effects of nephritis in man.

Regarding the results of Polvogt, McCollum, and Simmonds in their rat-feeding experiments, they state unequivocally that the high protein diets produced an unfavorable influence upon the kidney tissues.

In the observations of Drummond, Crowder, and Hill, as quoted, the kidneys were examined after 100 days of feeding. I doubt whether that period was long enough to produce the characteristic results. In our work and that of Polvogt et al., the periods were much longer—from six months to fifteen months, in our experiments. In the report of Osborne and Mendel on experiments for the purpose of determining the effect of diets deficient in preformed carbohydrates, there is no detailed information as to what proportion of the animals were examined histologically or at what stage in the feeding the kidneys were thus examined.

Doctor Kilgore very properly emphasizes the importance of unbiased observation of suspected lesions. We purposely made our microscopic observations under conditions which would insure this. No information was available, to the one of us who did the microscopic work, as to the nature of the diet in any given case until after the observations were made. The dead rats were brought to the pathology laboratory and recorded by number only. Under these working conditions, no abnormalities were recorded in the ten control animals on the normal ration. The lesions presented in the photographs shown illustrate the conditions observed in the animals with the abnormal diets.

Tinkering With Health by Tinkering With Milk—

The California legislature shows poor judgment in starting out to solve the really serious and extensive milk problem by attempting to tell the hospitals what kind of containers their milk may be served in. Hospitals have the facilities and are perfectly competent to judge the quality of food, drink or medicine they serve their patients. Furthermore, they are already legally responsible for any untoward results that may happen to their people because of carelessness or ignorance.

California certainly does need, and needs badly, some intelligent legislation upon its milk problem, but before such legislation can be worth while there must be better enforcement of some of the existing complicated laws upon the subject and an intelligent report prepared by personally disinterested thoroughly qualified students.

There are several public health features of milk more important than that it shall be served only in certain kinds of containers. The typhoid germ grows just as luxuriantly in a quart bottle of milk as in a tin can, and, furthermore, it is no respecter of labels. These germs have recently grown in milk in bottles and other containers to the cost of health and life in our state and elsewhere.

And We Call Ourselves "Free"—"Thirty years from now, if we continue at the present riotous rate, taxes will be \$100 per capita," says Senator Borah, "and 40 per cent of the national income will be demanded for public expenses. There will be an officer for every ten persons in the republic, and in every activity we will find ourselves under the surveillance of a bureau. We will still have a republic in name, but a bureaucracy in fact—the most wasteful, the most extravagant, the most demoralizing and deadly form of government which God has ever permitted to torture the human family."—*Illinois Medical Journal*.

Doctor or M. D.—The title of Doctor seems to have little significance any more, since it may be applied to the osteopath, the chiropractor, the optometrist, and a vast army of less well known but insufficiently qualified practitioners of the healing art. It is, therefore, of real importance that the Doctor of Medicine be careful always to distinguish himself by his degree of M. D. rather than merely by the meaningless title of Doctor.—*The Atlantic Medical Journal*, March 1925, Editorial.

CONGENITAL NASAL ATRESIA

By FRANCIS L. ROGERS, M. D., Long Beach, Calif.

It is important that the nasal tract anteriorly and posteriorly be cleared of obstructions prior to the operation for atresia.

The removal of a section of the posterior end of the nasal septum is important in securing a free and permanent opening.

The effect of continuous mouth-breathing upon the nutrition and general health of the child is very marked. In bilateral atresia narium cases, the very prompt and marked improvement in this case illustrates the point that in these cases imperfect oxygenization and physical exhaustion from labored breathing, rather than infections, are the greatest factor unfavorably influencing general nutrition of the child.

A better understanding of this condition, careful routine examinations of the nose, with a probe at birth by obstetricians, would no doubt reduce infant mortality and relieve embarrassment resulting from faulty diagnosis by family doctor or pediatricist, and generally conduce to greater efficiency in our profession.

DISCUSSION by Harvard McNaught and C. Edgerton Carter.

JUDGED by the available literature on the subject, congenital nasal atresia is a rare condition. Many nose and throat textbooks do not even mention it. Others of a considerable number examined give it but very brief mention. Otto, in 1830, was the first to discover the condition which he found at post mortem. It was first reported in a living subject in 1854 by Emmert. Schmiellglow, in 1904, first tabulated a list by collecting sixty-four cases, and up to the present time (1924) there have been about 165 cases reported in the literature of all countries.

In a questionnaire presented to a group of forty nose and throat specialists recently, but two reported ever having seen a case of congenital bilateral atresia of the nasopharynx.

The cause of congenital atresia of the choana is somewhat clothed in doubt, but it is believed that the primitive nasal capsule which develops as a part of the primordial cranium, and which extends forward beyond the anterior portion of the notochord, forms a core for the frontal nasal process, producing a broad mass of tissue changed in form somewhat which approximates the lateral nasal and maxillary processes. By this approximation of the nasal structures, the ectodermal coverings are brought abnormally into contact, the processes become united and the atresia results. This all occurs in the early months of the intra-uterine life during the formation of the foetal head.

Nasal atresia is believed to be much more common than the present available literature would indicate. Some writers who have made an intensive study of the subject state their belief is that many deaths at birth, or within the first forty-eight hours after birth, where the cause of death is not positively known, are attributable to this form of asphyxiation. If this be true, the subject is one of very much greater importance than has heretofore been regarded, and offers added reason for bringing the subject to the attention of the profession, particularly to obstetricians, general practitioners as well as the rhino-laryngologist.

Richards says mouth-breathing is always an ac-

quired habit. Hence, a child born with complete nasal obstruction almost immediately becomes cyanotic and in distress cries. The crying establishes mouth-breathing, which temporarily relieves the cyanosis. When the child stops crying it soon becomes cyanotic again, and it frequently becomes necessary to aid the child's early respiratory acts by mechanically elevating the soft palate and pulling the tongue forward, repeating the practice until the mouth-breathing habit is acquired.

Statistics compiled in 1918 by McNaught of San Francisco indicate that the condition occurs more often on the right than on the left side, and much more often unilaterally than bilaterally, but accurate percentages for either are not available.

When one nostril is occluded, the patient may not manifest the most marked symptoms of obstruction. Where atresia is complete on both sides, mouth-breathing is the most conspicuous symptom. The persistent presence of secretions of a peculiarly opaque mucilaginous consistency in the nose which cannot be expelled by blowing the nose, or the appearance of a watery discharge from the nose when the child cries from increased lachrymation, should always suggest the presence of congenital nasal atresia. Headache, deafness, and anosmia are said to exist in most cases, but were not observed in any of the three cases I shall report. The presence of adenoids, polypi, or other tumors benign or malignant, should always be determined and ruled out in every case of suspected atresia.

The treatment of congenital atresia is fundamentally surgical. Authorities differ somewhat as to the time of choice, varying from the first to the tenth year. A majority agree that it should be undertaken as early in life as there is sufficient development to admit the operator's forefinger into the nasopharynx, and the nostril large enough to admit of visualizing the field of operation and the use of instruments required in the nose at the point of occlusion.

I have seen and recognized, in thirty years' practice as a rhinologist, three cases of complete atresia of the choana narium. The first case was seen in 1897, the second in 1907, and the last—the principal subject of this paper—November 5, 1921. The first two were unilateral, the last was bilateral. All three occurred in females, and all were under 10 years of age.

The first case, in a well-developed child of 4 years, was unilateral and on the left side. The parents were healthy farming people in the Middle West.

The second case was a girl of 7 years, the daughter of an Italian musician residing in Long Beach, California. The atresia was on the left side, and was complete. This case was operated, using a technique then recommended in textbooks, but with a result not wholly satisfactory, the lumen of the choanae when healed being smaller than was desired, resulting in a slight whistling sound when mouth was closed and patient was taking exercise.

The third, Harriet H. was born January 4, 1917, in a Brooklyn, New York, hospital. She was a first child. There is no history of hereditary disease or abnormality in parents, both being strong, healthy young Americans, aged about 22 years. The child

was a "war baby" and weighed at birth twelve pounds. Delivery was very tedious, lasting four days, but was completed without instrumentation. From the moment of birth, the child had great difficulty in breathing. Almost constant attention of a nurse was required for several days to relieve attacks of choking and cyanosis. It does not appear from any history obtainable that the real cause was discovered at that time. At the age of 11 months, and again at 2½ years, adenoids were diagnosed and removed without general anesthesia at Brooklyn and New York clinics. Neither operation seemed to have afforded any material relief to the patient, and no intimation was ever given the mother of the discovery of any other cause for her constant mouth-breathing and other symptoms. The case was referred to me by a colleague November 5, 1921, with the suggestion that she had adenoids and infected tonsils. Tonsillectomy was performed under general anesthesia on November 8, 1921. No adenoids were found, but the real cause, a bilateral nasal atresia, was discovered, located at or about opposite the pos-

Before operation

After operation

terior end of the vomer. The nasopharynx was rather shallow, but of average width. The occluding wall was firm, smooth and bony, free from granular vegetations or other evidence of disease. The end of the vomer projected slightly backward, forming a well-defined central ridge somewhat wider than the normal edge of the nasal septum. I informed the mother of the condition present and nothing further was attempted until April 18, 1922, when under ether anesthesia the case was operated, and we believe the defect most successfully remedied by the following procedure:

Both anterior nares were cleansed and packed with gauze soaked in a 1-3000 solution of adrenalin. With a well-darkened operating-room, a hooded lamp, and a head-mirror, I was able to visualize the field of operation in both nostrils very well. The left middle turbinate was found oversize, the lower margin being twisted and tightly pressing against the nasal septum, opposite which a small bony spur projected. The turbinate was removed, likewise a

small button of the bony septum opposite it was resected submucously. This provided a clear field on both sides. An incision through the overlying mucous membranes was made from top to bottom of the septum at the junction of the septum with the occluding bony wall, continuing it across the floor to the outer wall of each nostril. Elevating the membranes, including the periosteal covering of the false bony wall, each was turned in a flap outward and forward against the outer nasal wall. From the primary incisions the mucous membrane and periosteum were then dissected forward on septum and floor about one-fourth of an inch. At that point the bony septum was cut through parallel to the primary incisions. The angular knife and a Freer chisel made the horizontal cut across the floor and upward along the outer wall and vault. The false bony walls were then removed through the nasopharynx with a forceps, using the forefinger in nasopharynx as a guide. A small glass pipette on the regular Yankauer suction apparatus served well to keep the nasal field free from blood and mucus. All bony edges were then carefully smoothed with a curette, and the deflected mucous membrane folded backward over the denuded bony surfaces. A three-eighths inch rubber drainage tube was placed in the floor of each nostril, extending well into the pharynx and projecting one-half inch outside the nasal opening. Two folds of half-inch gauze were impregnated with albolin and were inserted in nostrils above the tubes. A strip of O. Z. adhesive, three-fourths inch wide, was placed from cheek to cheek under the tip of the nose, to which the projecting rubber tubes were stitched for added security. Alkaline irrigations through the tubes were used daily after the second day. Gauze packing was removed on the third day, drainage tubes removed for cleansing and replaced on the sixth day and permanently removed on the eighth day, after which daily irrigations and practice in nasal breathing were begun and have since been kept up with regularity. The child had to be taught to blow its nose and to breathe nasally, but at no time after removal of packing was there any occlusion of either nostril that was not readily relieved by irrigation.

From birth the child had been sallow, pale, undernourished, restless at all times, and mentally retarded. Her facial expression suggested the simple-minded. She was nearly four years old before able to make words into sentences, and until last operation her speech was so imperfect as scarcely to be understood even by her mother. When last examined, June 10, 1922, she was able to breathe comfortably from either nostril with mouth closed, and to sleep with closed lips. She now speaks quite distinctly, has an increasingly good vocabulary, is mentally alert, and her general physical condition has improved greatly. The mother, who is the wife of a naval officer, moved to Seattle, Washington, but reported regularly once each month until July 1, 1923, reporting that her condition in every way seemed that of a normal child. On March 20, 1924, I wrote the mother, requesting a final report and requesting that she take the child to Dr. J. Thomas Dowling of Seattle for a critical examination, and his report to me is as follows: "I am pleased to report that her

nose is in fine condition. She breathes quite normally, as a child should with a normal nose. I think your work has been entirely successful."

SUMMARY

1. It is important that the nasal tract anteriorly and posteriorly be cleared of obstructions prior to the operation for atresia.

2. The removal of a section of the posterior end of the nasal septum, which in this case was considerably thickened, is important in securing a free and permanent opening.

3. The effect of continuous mouth-breathing upon the nutrition and general health of the child is very marked in bilateral atresia narium cases. The very prompt and marked improvement in this case illustrates the point that in these cases imperfect oxygenization and physical exhaustion from labored breathing, rather than infections, are the greatest factor unfavorably influencing the general nutrition of the child.

4. A better understanding of this condition, careful routine examinations of the nose with a probe at birth by obstetricians, would no doubt reduce infant mortality and relieve embarrassment resulting from faulty diagnosis by family doctor or pediatricist, and generally conduce to greater efficiency in our profession.

DISCUSSION

HARVARD McNAUGHT—Congenital occlusion of the nares probably occurs much more frequently than is supposed. The reported cases are comparatively few, but the discovery of some cases, post mortem, leads me to think that it is more common than the statistics would indicate. Obstetricians and pediatricians should be on the lookout for the cycle first described by Richardson and referred to in the foregoing paper, viz.: cyanosis—crying, which relieves the cyanosis, and so on, and when this is seen, think of this condition.

My own experience has been confined to three cases: one of complete unilateral bony occlusion, and two of partial, incomplete cartilaginous occlusion, all in adults. The two cartilaginous ones were easily corrected, as the septal occlusions were then easily bitten out. No attempt was made to make a mucous membrane flap, as the cartilaginous edges do not show the tendency to granulate that bone does. The case of bony occlusion, however, which I described in a paper read before the California State Medical Society, April, 1917, presented a different problem. This patient was operated by me in January, 1915, by a method I had conceived, viz.: to approach the occlusion by means of a submucous septum operation, extending dissection over the anterior face of the bony wall, and after removing the wall use the membrane to cover the floor and roof of the choana. The execution of the operation was easy until I attempted to remove the bony occlusion, which was found too thick to bite out, and chiseling was deemed dangerous owing to the proximity of the eustachian tube. I then improvised the method which Doctor Rogers has advocated—removal of part of the posterior edge of the nasal septum, which gave complete relief to the patient and did not close. This operation was conceived and performed January, 1915.

In April, 1915, Thomasson independently described an operation essentially similar to mine. I relate this case to call attention to the possibility of meeting with a very thick wall and to endorse the remarks of Doctor Rogers in regard to removing a part of the posterior edge of the septum. Where the wall is thin, an operation such as I

originally intended could easily be done, and should prevent undue closure from granulation.

C. EDGERTON CARTER, M.D. (Brockman Building, Los Angeles)—Congenital nasal atresia, as presented by Dr. Rogers, is distinctly a contribution to the literature of congenital malformations.

To the pediatricist, the congenitally cyanotic infant naturally suggests deficiency of the circulatory or respiratory system or both. That this condition may result from complete occlusion of the posterior nares, is not so well appreciated.

The paucity of case reports by no means reassures us that unilateral atresias, at least, may not have been overlooked within our own experience.

At any rate, Dr. Rogers' report will put us on our guard that no "blue babies" escape this amplification of our differential diagnosis.

This one symptom of cyanosis, which ceases during crying or mouth-breathing, differentiates nasal atresia from cardiac incompetence.

Atelectasis, the other not infrequent respiratory complication, reveals in the infant a rapid, shallow respiration, with cyanosis constantly present, though varying in intensity. Radiographs, of course, further illumine the clinical picture, be it cardiac or respiratory.

One feature perhaps not sufficiently emphasized in Dr. Rogers' able article is that of early diagnosis. The comparatively simple procedure of incising the occluding post-nasal membrane with immediate relief of the suffocative and irritative symptoms is so pre-eminently preferable in our judgment to that of an operation delayed for years, that the writer wishes to heartily second Dr. Rogers in advocating a more careful early differential diagnosis.

Furthermore, there is a mental and physical retardation aside from the resulting developmental deficiency which makes early diagnosis desirable.

These three reported cases were aged 4, 7, and 5 years, respectively, and undoubtedly were correspondingly handicapped during the pre-operative years.

The operative technique elaborated by Dr. Rogers impresses one as comparatively simple, effective, and practical for the skilled operator.

DOCTOR ROGERS (closing)—I cannot but feel gratified at these approving expressions from the gentlemen who have discussed my paper. If their words and what I have gleaned from a rather meager literature and a necessarily limited personal experience concerning congenital nasal atresia serves to arouse the obstetricians, pediatricists, rhinologists, and the greater body of general practitioners who read CALIFORNIA AND WESTERN MEDICINE to a realization that many deaths heretofore registered as "still births," "heart failures," "blue babies," and "cause of death unknown" may be and probably are cases of nasal atresia, then this paper and discussion will seem worth while.

To the equipment of every obstetrician, I would suggest be added a small six-inch ball-pointed silver probe, and recommend that their duty be not complete in any case until they have passed this probe into the mouth by way of each nostril of every new-born baby they deliver. The procedure is simple and practically painless, and will promptly recognize any nasal occlusion and direct a course of action that will save the life of many and perhaps all such defectives who otherwise may not live longer than a few minutes, hours, or days.

Herbalogists Arrested Again—Some of the "Herb" "Doctors" have been again arrested for practicing medicine without a license. "Besides selling herbs, it is charged the 'doctors' diagnosed ailments which is against the law. They were released on a \$100 cash bail by Police Judge Lazarus."

Some of these "Chinese Herbalogists" openly advertise their illegal claims in matter that circulates in the United States mails. We will tell the outcome of these arrests later.

THE INTENSIVE TREATMENT OF CONGENITAL SYPHILIS (FINAL REPORT)

By HERMANN SCHUSSLER, JR., M. D., *San Francisco*

(From the Division of Pediatrics, Stanford University
Medical School)

A safe and efficient plan of treatment for congenital syphilis, with suitable variations for special types, is presented.

The methods described are easy to carry out, require very little apparatus or technical skill, and cause practically no discomfort to the patient.

The principle involved is a series of vigorous attacks on the spirochete, with the various available remedies, as the best means of avoiding the Wassermann-fast state.

The evolution of the method during 1920-1922, and its extensive use since then, both in private practice and several clinics, has been followed by eminently satisfactory clinical and serological results. It is therefore recommended for routine use in general and pediatric practice.

DISCUSSION by Harold K. Faber, *San Francisco*; Laurence Taussig, *San Francisco*; M. L. Cohn, *San Francisco*; L. J. Schermerhorn, *San Francisco*; Langley Porter, *San Francisco*.

FEW of the recent articles on congenital syphilis are particularly hopeful as regards prognosis, while several have been frankly pessimistic in tone. In a previous paper, published in this journal in August, 1922, I suggested that one reason for this might be a more or less hesitant attitude, on the part of most physicians, toward the employment of intensive therapeutic measures in infancy and childhood, comparable to those commonly used with adults. This hesitancy is based on several rather firmly rooted prejudices in the minds of physicians in general, which might be formulated somewhat as follows: (1) That intravenous injections in infants and children are painful and technically difficult. (2) That large and frequent doses of the organic arsenicals cause serious damage to the liver and other organs in the young. (3) That the co-operation of parents and school teachers, to say nothing of the children themselves, cannot be secured over a sufficiently long period. (4) That late hereditary syphilis is so resistant to treatment that the effort is not worth while.

In my earlier paper I outlined the plan of treatment in use in the Children's Clinic of the Stanford University Medical School, and indicated that excellent clinical and serological results had been obtained in many patients up to that time. In the subsequent two years several improvements have been made in the routine plan, a few variations have been developed to apply to individual cases, and the results as a whole have been so satisfactory that this appears to be an opportune time to present them in a resumé of four years of work.

For therapeutic purposes, the cases are classified as follows: (1) Infants under one year; (2) Children over one year; (3) Interstitial keratitis cases; (4) Wassermann-fast cases; (5) Older children with neurosyphilis. In the first three groups the

course begins with a series of eight intravenous injections of neoarsphenamine in concentrated solution, given at the rate of three a week. For the next eight weeks mercurial inunctions are given twice a week for babies, covering most of the body each time, and three times a week for older children, covering about one-third of the body each time. These rubbings last half an hour, and minute instructions are given to the parents. For the interstitial keratitis cases, intravenous injections of novasurol are given twice a week for eight weeks instead of inunctions. During the neoarsphenamine and mercurial courses, a saturated potassium iodide solution is given in milk three times a day with meals, the dose being one drop (one-half minim) per year of age. This is omitted during the first year of life. A two weeks' rest is allowed after the mercurial course, after which a Wassermann test is done, and the whole course repeated. Thus a Wassermann is done every three months, four courses being given in a year.

Sulpharsphenamine or neoarsphenamine may be given intramuscularly twice a week for eight doses to those infants whose veins are inaccessible. The results are quite as satisfactory as from the intravenous method, using the same dosage and concentration; and there seems to be no pain or local irritation, the baby often going to sleep at once.

For Wassermann-fast and neurosyphilitic children, the plan of treatment is radically changed. The child attends the clinic twice a week for eight weeks. On Tuesday he gets an intravenous injection of sulpharsphenamine 0.4-0.8 g., and an intramuscular injection of bichloridol 0.06 g. On Saturday he gets an intravenous injection of silver salvarsan 0.1-0.3 g., and an intramuscular injection of bismudol 0.2 g. This alternation, which was suggested to me by Baketel of New York, has given excellent results. The intramuscular injections are given into the gluteus medius about an inch above the tip of the trochanter, and are very well borne. Potassium iodide is given throughout in full doses. A month's rest follows each course.

Treatment is continued until two successive rest periods have been followed by completely negative Wassermanns, using a very sensitive method. If clinical signs have also cleared up, active treatment is stopped at this point, but mercury protoiodide is given by mouth for two more months to older children. A Wassermann is then taken every six months for three years. No case is dismissed as probably cured unless all these tests have been negative and there have been no clinical relapses. Lumbar puncture is done only when there is a clear indication for it.

I have used three standard brands of neoarsphenamine, and am unable to note any marked difference between them as regards toxicity and therapeutic efficiency. There is some variation in subjective taste and smell, solubility, and content of foreign particles, but these are of minor importance.

Neoarsphenamine and sulpharsphenamine are given in 30 per cent solution, the dosage being based on body weight, as well as on individual arsenical tolerance, as estimated by a somewhat smaller initial

dose. This is about two-thirds of the regular dosage, which is given in the accompanying table:

Weight:	Under 12 lbs.	12-24 lbs.	24-36 lbs.	36-48 lbs.	48-60 lbs.	Over 60 lbs.
Dosage:	0.15 g.	0.3 g.	0.45 g.	0.6 g.	0.75 g.	0.9 g.
Water:	0.5 cc.	1.0 cc.	1.5 cc.	2.0 cc.	2.5 cc.	3.0 cc.

TABLE I. SCHEDULE OF DOSAGE FOR
NEOARSPHENAMINE

This dosage may seem excessive, according to adult standards, but it must be remembered that arsenical tolerance in infancy and childhood is relatively high, and that late congenital syphilitics very readily become Wassermann-fast when treatment is prolonged, but inadequate. Immediate or nitritoid crises are very rare, and none have been severe enough to require treatment. Silver salvarsan is given in 5 per cent solution, the full dose being one-third that of neoarsphenamine for the same patient. The initial dose is 0.1 g., and subsequent doses increase by 0.05 g. each time up to the full dose. This gradual increase is very important, and will prevent some unpleasant experiences with this preparation.

The technique is as follows with all these arsenicals: A 5 cc. Luer syringe and a 25 gauge, one-half inch needle are sterilized, and the proper amount of cool, freshly boiled water is drawn up. Freshly distilled water is necessary for silver salvarsan, but tap water is perfectly satisfactory for neoarsphenamine and sulpharsphenamine, which are given in practically equal doses. The tip of the ampule is filed off, and the water forcibly injected through the resulting opening. The ampule is now shaken, with a sterile finger over the hole, until solution is complete, but not longer than this. It is then inverted, the needle inserted, and the solution aspirated into the syringe. It is at once injected into any available vein in the usual manner. The temporal or occipital veins are the best in babies, the head being firmly held and a 2 cc. Luer being used. In older children the veins at the bend of the elbow are often as good as in adults. Between these ages the larger of the two external jugulars is the vein of choice. It is brought into prominence by hyperextending and rotating the head, with a pillow under the shoulders. The needle is inserted during a cry, which distends the vein. Unless blood comes back freely no attempt should be made to inject. In children old enough to reason with, the time spent in gaining the child's full confidence and co-operation, and in overcoming his initial fear of the procedure, will prove to be a very profitable investment. My older children take their injections while sitting in a chair, and there is practically never any outcry or struggle, as the tiny needle is scarcely felt. The unpleasant taste and smell disappear if the child holds his nose and breathes through his mouth during the injection.

Mercury inunctions are given in the usual manner. Emphasis is placed on the necessity of giving the inunctions over a very large area, as the mercury is absorbed only through the pores and hair follicles. Mercurial "olives" are used, the dose being 2 to 4 g., according to age. The potassium iodide solution is dropped slowly into a full glass of milk, which is

constantly stirred during this time to insure thorough mixing, and sweetened if necessary.

The intravenous injections of novasurol, which have proved of particular value in interstitial keratitis, are given in ascending dosage. The ampule holds 1.2 cc. The first dose is 0.6 cc., the second 0.9 cc., and all subsequent doses 1.2 cc. Renal irritation is very unusual, and never lasts more than a week after stopping the mercurial. In interstitial keratitis, the preliminary neoarsphenamine course seems to prevent involvement of the second eye in unilateral cases, while the novasurol clears up the acute symptoms and ultimately the opacities. Old cases, of course, respond slowly, but recent cases attain normal vision in a few months.

Novasurol is injected directly, without dilution, using the same 2 cc. Luer and small needle as are employed for neoarsphenamine. It is absolutely non-irritating to the vein. As stated above, two injections a week are given for eight weeks, following each arsenical course.

Untoward effects from the routine plan of treatment have been very infrequent. There have been some patients who could not tolerate iodides, while a few developed a mild dermatitis from neoarsphenamine. These cases all cleared up rapidly under the sodium thiosulphate treatment recommended by McBride and Dennie. Our only fatality traceable to the treatment occurred from intercurrent pneumonia developing in a case of severe toxic jaundice. The patient, a hopeless juvenile paretic, was given a very intensive course of the mixture of neoarsphenamine and bichloride advised by Linser of Tübingen. (We tried this method for a while, but abandoned it as both inefficient and dangerous.) With these few exceptions, I cannot recall one child who seems to have been damaged by the treatment, which seems rather to have a tonic effect.

The clinical and serological results have been very gratifying. As shown in the table, all infants under one year of age have become persistently negative after one or two courses. Of the adequately treated older children, 65 per cent have become and remained negative, 8 per cent became negative, but relapsed, and 27 per cent are Wassermann-fast. The observation period in the negative cases has lasted from a few months to four years without treatment. No case has relapsed after being constantly negative for a year. Of twelve well-treated cases of interstitial keratitis, nine now have normal vision, and three (all old cases) are improving. Of four unilateral cases, the second eye became involved in only one. This boy received no neo. before his first mercurial course. Two small infants died of intercurrent disease, one of broncho-pneumonia, and one of dysentery.

TABLE II

Serological Results in Infants Under One Year	
Total infants treated.....	15
Died of intercurrent disease.....	2
Negative after one course.....	12
Negative after two courses.....	1
Serological relapses.....	0

TABLE III

Serological Results in Children Over One Year	
Total children treated.....	87
Disappeared from observation.....	17
Recently began treatment.....	15
Died.....	1
Adequately treated cases.....	54
Became and remained negative.....	35 65%

Became negative but relapsed.....	4	8%
Wassermann-fast to date.....	15	27%

TABLE IV

Results in Interstitial Keratitis		
Total cases treated.....	13	
Disappeared from observation.....	1	
Normal vision restored.....	9	
Improving (old opacities).....	3	
Second eye involved during treatment.....	1	

Particularly notable has been the clinical improvement in these cases. Bone lesions and paralyses have disappeared, nutrition and weight and color have improved remarkably, and the whole appearance of the patients has changed for the better. One girl gained thirty pounds during her third year of treatment, having gained comparatively little before this. The teachers report better scholarship and conduct under treatment, and all who have seen the results feel that the work has been of great value.

SUMMARY AND CONCLUSIONS

A safe and efficient plan of treatment for congenital syphilis, with suitable variations for special types, is presented.

The methods described are easy to carry out, require very little apparatus or technical skill, and cause practically no discomfort to the patient.

The principle involved is a series of vigorous attacks on the spirochete with the various available remedies, as the best means of avoiding the Wassermann-fast state.

The evolution of the method during 1920-1922, and its extensive use since then, both in private practice and in several clinics, has been followed by eminently satisfactory clinical and serological results. It is therefore recommended for routine use in general and pediatric practice.

Fitzhugh Building.

DISCUSSION

HAROLD K. FABER, M. D. (Stanford University Medical School, San Francisco)—Up to the last few years congenital syphilis was rightly regarded as one of the more intractable forms of the infection, and prognosis had to be given in the most guarded terms. Such results as Dr. Schussler has shown justify a much more hopeful outlook and represent a real triumph in therapy. They have been obtained not only by systematization and persistence, but by a radical increase in dosage, the initiation of which required faith and courage in the face of adverse criticism. I have watched from the first, with interest and approval, Dr. Schussler's well-planned and vigorous method of attack against a disease which is both widespread and deeply rooted at the earliest moment when measures can be directed against it and have been deeply gratified by the success he has obtained, so amply demonstrated in the present paper. It should be emphasized that the method is simple enough to be used by any physician with some skill in intravenous technique with children, though Dr. Schussler's unusual proficiency has been an important factor in the success he has obtained.

LAURENCE TAUSSIG, M. D. (380 Post Street, San Francisco)—It has impressed itself upon us for some time that conscientious, persistent antiluetic therapy could cure a certain proportion of children with hereditary syphilis. As in other forms of late lues, the most important therapeutic agent is mercury. The form in which it is given is of relatively little importance, though I should place properly administered mercury rubs first, insoluble mercury injections, administered intramuscularly, second, and mercury by mouth last. I have had no experience with intravenous mercury, but can see no advantage in its use. I do not think that it matters much whether we give sulpharsphenamine intramuscularly or neoarsphenamine intravenously, providing a number of doses are given at

regular intervals. Our routine course at Children's Hospital recently has been to give 0.1 to 0.3 of sulpharsphenamine at weekly intervals for six or eight doses, and then bichloridol gr. ¼ to gr. 1 at weekly intervals for twelve to eighteen doses. Our series is too small and too recent to compare the results with those reports in this paper, though the results appear to be good so far. It seems to me that the important point that Schussler has brought to our attention and emphasized is, that the conscientious treatment of congenital syphilis is well worth undertaking, and that the earlier we start and the more faithful we and our patients are the better our chance of benefiting the members of this class of unfortunates. I am not convinced that Schussler's rather radical neoarsphenamine dosage is necessary, even though it has proven safe.

M. L. COHN, M. D. (240 Stockton Street, San Francisco)—I have keenly enjoyed the paper of Dr. Schussler and believe it will be of untold assistance to many practitioners who are prone toward pessimism in the prognosis of congenital syphilis. It will also be of extreme value to those men who have no systematic routine in the treatment of this condition, and to those who are skeptical regarding the safety of such intensive treatment.

For the past few years I have treated a large number of congenital syphilitic children at the Children's Clinic, University of California Hospital. My routine has not been so intensive as that advocated by Dr. Schussler, and perhaps the time element has been prolonged, but the results are ultimately quite comparable.

Each practitioner has his individual conception of the treatment of congenital syphilis, most procedures based upon the use of the two drugs—mercury and arsenic—and each method possessing its respective merits.

The most valuable factor in treating congenital syphilis, and the one least considered, is the co-operation of parent and patient. When this condition has been fulfilled it makes little difference which of the arsenicals and mercurial preparations are used, providing adequate dosage is administered over a sufficiently long period of time.

L. J. SCHERMERHORN, M. D. (516 Sutter Street, San Francisco)—During the past five years I have had about seventy-five cases of congenital syphilis under observation and treatment. I am firmly convinced that, to get satisfactory results from treatment, it is necessary to use large doses of either salvarsan, neosalvarsan, silver salvarsan, or neutral salvarsan in combination with mercury and the iodides, and in certain cases bismuth.

Dr. Schussler's plan of treatment is an excellent one, and one that can be followed with comparative safety. However, one must be on the lookout for complications and not take unnecessary chances in pushing the drugs beyond the patient's tolerance.

More negative Wassermans are obtained if, after the first course of neosalvarsan is given, salvarsan or silver salvarsan is used for the second course, and the third course may be a combination of neosalvarsan and any one of the other salvarsans. Mercury is as necessary as arsenic. Mercurial inunctions are the method of choice if the parents will co-operate with the doctor; if not, intramuscular injections of insoluble mercury are to be preferred. Schussler's results are the result of conscientious, persistent treatment, and his methods are a step forward in the treatment of congenital syphilis.

LANGLEY PORTER, M. D. (380 Post Street, San Francisco)—It is refreshing to come upon a paper written as this one of Dr. Schussler's is, from the standpoint of a clinician amply experienced in the subject matter of his essay. Nothing can be more valuable than this contribution, and its value lies no less in the demonstration of the worth of well-organized university clinics devoted to the special study of single diseases (clinics where adequate material is bound to accumulate) than in the painstaking report of success the clinician's long labor won in this difficult field.

Thanks to the activities of obstetricians and syphilographers who deal with adults, patients with congenital syphilis are much fewer than formerly, so that to gather and bring under treatment so many cases of congenital syphilis is an achievement in itself hardly less to be applauded than the success that has attended the persistence of Dr. Schussler in his line of therapeutics.

The report marks the writer's familiarity with the most

recent works of other clinicians, and it is of importance that he is able to confirm the observation that bismuth is effective in overcoming the factors that produce persistence of the Wassermann reaction in resistant cases.

This contribution will be of great practical value to the profession and a great aid to the pitiable victims of congenital lues because the detailed descriptions of methods and modes make the treatment, as practiced by the writer, available to any one in the profession. It is a real contribution, an honor to the writer and to the medical school he so ably represents.

DR. SCHUSSLER (closing)—I am glad that my paper has brought out such an interesting discussion, which strongly emphasizes the curability of the disease under intensive and persistent treatment. The large doses and short intervals which I now use have been reached by a gradual evolutionary process, and I feel very strongly that they are necessary to secure the best results. Practically all my Wassermann-fast patients were started on relatively mild and inefficient treatment several years ago, and their spirochetes are now resistant to both arsenic and mercury. By way of contrast, out of ten strongly positive older children who were given an intensive first course about six months ago, nine were completely negative at the end of the rest period, while the tenth was still weakly positive. As the question of inunctions versus injections came up, I may add that I have practically given up inunctions since the paper was written. I now give infants a weekly intramuscular injection of bichloridol 0.01-0.015 g. for eight weeks after each neoarsphenamine course. Older children get ten weekly intramuscular injections of a mixture of bichloridol 0.06-0.12 g. and bisnudol 0.2 g. in the same syringe. This is practically painless, only the first injection causing any noticeable discomfort, and no toxic effects have been noted. The eight neoarsphenamine injections are given during the first three weeks of the mercury-bismuth course, with iodide by mouth throughout. The rest period is one month in all patients, a tonic being given if necessary. I find the gluteus medius more satisfactory in some cases, and the gluteus maximus in others. I have found intravenous injections of novasurol very valuable in rapidly controlling severe ocular lesions, such as interstitial keratitis. Perhaps bichloridol and bisnudol in full doses will prove equally efficient. Sulpharsphenamine has proved superior to neoarsphenamine in these eye cases.

Let me emphasize again that the general practitioner can now cure at least 80 per cent of his congenital syphilitic patients without difficulty, pain, or danger; and more than one year of treatment is rarely necessary. I can therefore see no excuse, even in isolated communities, for allowing these unfortunates to go untreated.

HEALTH OFFICERS APPOINTED

According to the California State Board of Health Weekly Bulletin, the following health officers have been appointed:

Mr. M. B. Ordway has been appointed health officer of Pacific Grove to succeed Mr. Frank B. Wilcoxson. Mr. Ordway is not recorded as being licensed to practice medicine in California.

Mr. M. G. Frost has been appointed health officer of Placerville to succeed Mr. Roy McCall. Neither Mr. Frost nor Mr. McCall are recorded as being licensed to practice medicine in California.

Dr. J. T. Christian of Galt has been appointed health officer of Sacramento County to succeed Dr. George H. Sanderson of Folsom. Dr. Christian is licensed to practice medicine and surgery in California, but is not a member of the California Medical Association at this time. Dr. Sanderson is a member.

Dr. E. W. Westphal has been appointed health officer of the newly incorporated city of Atherton, San Mateo County, postoffice Menlo Park. Dr. Westphal is not reported as licensed to practice medicine and surgery in California. He is not a member of the California Medical Association.

Most of the shadows of this life are caused by standing in our own sunshine.—Emerson.

SECONDARY HYPERTROPHIC OSTEOARTHROPATHY FOLLOWING METASTATIC SARCOMA OF THE LUNG

REPORT OF A CASE

By LLOYD BRYAN, M. D., San Francisco

The majority of authors are agreed that this condition is caused by a long-continued hyperemia secondary to an interthoracic condition in addition to a toxemia secondary to the primary disease.

The course of the condition is extremely variable. It may subside and entirely disappear with healing of the primary lesion, or it may progress independently of the original disease with the bone picture at the end not unlike that of osteitis deformans.

DISCUSSION by Leo Eloesser, San Francisco, and W. R. P. Clark, San Francisco.

SECONDARY hypertrophic osteoarthropathy has been recognized as a distinct clinical entity since the original papers of Bamberger (1889 and 1891) and of Marie (1890) and its relation to the simple clubbing of the fingers definitely established by the excellent work of Locke in 1915.

The majority of authors are agreed that this condition is caused by a long-continued hyperemia secondary to an interthoracic condition, in addition to a toxemia secondary to the primary disease. While, as a rule, the primary lesion is a chronic one, usually tuberculosis, bronchiectasis, chronic lung abscess, chronic disease of the circulatory or alimentary tract, secondary hypertrophic osteoarthropathy may occur in a rather acute condition.

Hyman and Herrick report a case in a child of 28 months without any primary lesion being demonstrable. I have observed it in a boy of twelve with an acute lung abscess, which was treated surgically and completely cured in three months. In this patient, at the end of a year all signs of the secondary bone changes had disappeared.

The course of the condition is extremely variable. It may subside and entirely disappear with healing of the primary lesion, or it may progress independently of the original disease, with the bone picture at the end not unlike that of osteitis deformans. There may at times be periods of regression and progression corresponding to the course of the primary lesion. Clinically, the condition is characterized by soft tissue swelling, redness, tenderness and pain in the region of the joints. Roentgenologically, the only means by which the diagnosis is certain, the first findings are bur-like irregularity of the distal phalanges, and later a laminated ossifying periostitis involving first the fifth metatarsals and metacarpals, then the remaining metatarsals and metacarpals, and later the long bones, and finally all the bones of the skeleton. The diaphyses are primarily involved, but the epiphyses do not escape. The joints show first swelling and erosion of the cartilages, and at times complete destruction with ankylosis of the joint.

Saundby, Hall, Alexander, Cagnetto, Hasbrouck, Oliver and I have each reported one case of hypertrophic osteoarthropathy with sarcoma of the lung, and this case is reported to again emphasize that a fairly acute primary lesion may be responsible.

A. C., male; 25; Italian; carpenter—Entered the San Francisco Hospital August 18, 1922. Complaint: Pain and swelling just above right knee for two and one-half

months. Injured knee June 2, 1922, while climbing a ladder; almost constant pain since then. On June 13, 1922, swelling was 2 cm. in size. F. H.: Unimportant. P. H.: Patient single. Denies venereal disease. Patient has always been well. P. E.: Slight pyorrhea, moderate enlarged tonsils. Two small glands in anterior cervical triangle. Marked enlargement of the right inguinal glands. At inner aspect of lower end of right femur there is marked swelling about twice the size of a baseball. X-ray: Periosteal sarcoma. Patient refused amputation, was given deep x-ray therapy. Urine and blood normal. Re-entrance, August 7, 1923. Blood pressure normal. Wassermann, negative. Tumor ulcerated, horribly foul, size of a large cantaloupe, Welch bacillus contamination. Amputation, August 11, 1923, by Dr. Leo Eloesser, right leg, middle of the thigh. Post-operative: Patient made a good recovery, discharged October 3, 1923.

Re-entrance, October 29, 1923. P. I. about one and one-half months after operation, stiffness began to develop in all his joints, with swelling of the joints of his foot and hands; there was little pain. P. E.: Swelling of the joints, clubbing of the fingers. Patient cannot tightly clench his hand. Other findings practically the same as before. There is some stiffness in both elbows. Complaint: Increasing weakness. X-ray of chest on November 1, 1923, showed large, rounded, smooth tumor mass in lower one-half of right lung and a few smaller nodules elsewhere in the lung. Patient complains of difficulty of

swallowing. X-ray examination of head is negative; apparently, no metastasis in hypophysis. X-ray of joints shows marked osteoarthritis. Died February 23, 1924.

Autopsy by Dr. W. Ophuls—Strongly built, well-nourished young man about 25 years of age. The right leg amputated about one-third of femur, well healed. Stump of leg is distinctly swollen, rather hard brawny resistance. Edematous swelling posterior part of scrotum and thigh on right. Left leg very much swollen, showing similar solid edema and marked enlargement of all

toes, especially distal ends of them. Moderate edematous swelling of both forearms, especially left, and very marked enlargement of all fingers and marked clubbing at ends. Nose and ears fairly large. Lips slightly prominent, and chin is small. There is little hair on upper lip, chin, and sides of both cheeks. Pupils are widely dilated.

Skull rather small and round. Skull cap normal; shows some deep depression from Pacchionian granulations in summit. Pia mater on both sides show marked congestion and edema. Sella turcica and hypophysis normal. Large venous sinuses base of brain normal. Large arteries base of brain normal. Slight accumulation of slightly bloody fluid in lateral ventricles and few soft, rather large clots. Brain section: through all parts nothing abnormal.

Abdomen moderately distended; marked atrophy of subcutaneous fat. Muscles also show marked atrophy. Liver projects five fingers below costal margin, in fifth mammillary line. Left lobe about same distance below zyphoid. Lower border stomach at umbilicus. Transverse colon just below. About 50 cc. of clear fluid in the rectovesical pouch. Diaphragm at sixth rib on both sides.

Chest is very large and strongly arched. No calcification of cartilages of ribs. In anterior mediastinum attached to posterior surface sternum is large, white tumor nodule 7 x 5 cm.

In pericardium 300 cc. clear, light yellow fluid. In left pleura 100 cc. clear, light yellow fluid. The right pleura completely obliterated by very strong fibrous adhesions, in lower part of which is very large mass of tumors about size of two fists which is firmly attached to diaphragm to inside ribs and replaces large part right lower lobe. Bone is not deeply invaded anywhere. Small

nodule just in front of body of fifth dorsal vertebra; another nodule size walnut attached to third rib near spinal column. Oesophagus somewhat twisted at lower end, apparently by pull of adjoining tumor nodule, otherwise normal. Trachea and larynx contain some clear foamy mucus. Marked involvement lymph glands at root of lung. Left main bronchus invaded. Tumor has gone through wall and projects in shape of small polypus on inner surface. Large nodule in anterior mediastinum is attached to pericardium, but has not invaded it. Heart valves are normal; muscle, thin, dark brown, and flabby.

No scar at left apex. Left pleura studded with large tumor nodules, largest about 5 cm. in diameter. Left lung well filled with air, except for large area of collapse of left base. Some small nodules in lung tissue. Large nodule in hilus of lung about 8 cm. in diameter. Aorta small, otherwise normal. Thyroid gland small, otherwise normal. Right lung: no scar at right apex. Numerous large nodules in right lung. The largest one measures 12 cm. in diameter, and is in the right lower lobe. Spleen is large, $13 \times 9\frac{1}{2} \times 4$; cut surface shows very marked passive congestion. Left adrenal is small, otherwise normal. Left kidney—capsule strips easily—measures $12 \times 5\frac{1}{2} \times 3\frac{1}{2}$. Kidney shows a marked passive congestion. Right adrenal and right kidney same as left. Marked edema of pelvic connective tissue. Bladder contains some clear urine; shows a marked passive congestion and some edema. Prostate is normal. Rectum is normal. Duodenum and contents normal. Bile-duct is patent. Stomach contains some dark brown mucus; mucous membrane shows exceptionally heavy rugae. Pancreas small, otherwise normal. Gall-bladder and contents normal. Liver large, $26\frac{1}{2} \times 21\frac{1}{2} \times 7\frac{1}{2}$ cm. Cut surface: centers are dark and the peripheral parts light in color. Omentum is atrophied. Mesenteric lymph nodes normal. Retroperitoneal, iliac lymph nodes normal. Femoral lymph nodes moderately enlarged, congested, and edematous. Small intestine is normal. Large intestine shows marked passive congestion and edema. Appendix is normal.

Anatomical Diagnosis—1. Osteo-sarcoma periosteal femur. 2. Sarcoma metastatic of lung. 3. Edema lymphostatic of all extremities. 4. Osteo-arthritis, general. 5. Operation, amputation thigh. 6. Pleurisy, chronic adhesive.

Histological Examination—Pancreas: Normal, normal arteries. Hypophysis: Normal. Kidney: Very much congested, normal arteries, few small scars in cortex. Prostate: Normal. Liver: Moderate fatty infiltration in periphery of lobules, normal arteries. Spleen: Very marked congestion of venous capillaries, otherwise normal, normal arteries. Tumor: Consists of cellular fibrous tissue in which there is much osteoid tissue which is partly calcified; in places there are large giant cells, large areas of necrosis. Lung: Contains tumor nodule of similar structure. Colon: Very much congested, otherwise normal. Small Intestine: Normal.

I am indebted to Dr. Leo Eloesser for the privilege of reporting this case.

135 Stockton Street.

DISCUSSION

LEO ELOESSER, M. D. (135 Stockton Street, San Francisco) — The cause of secondary hypertrophic osteoarthropathy and its allied manifestation, clubbed fingers, is unknown. Neither venous stasis nor suppurative processes alone suffice to account for their origin. Most cases follow pulmonary suppuration, either tubercular or non-tubercular. Doctor Bryan's report is of peculiar interest because the patient was neither cyanotic nor did he have a suppurating focus at the time when his periostitic deposits first made their appearance.

Most secondary osteoarthropathies show exacerbations and remissions; thus patients with discharging empyemas not uncommonly complain of pain and swelling of their bones and joints whenever their chests drain insufficiently: when abscesses break out and drain freely pain and swelling recede. This would incline one to ascribe the origin of the arthropathy to an infectious element.

Typical unilateral club-fingers have been described, however, following subclavian aneurysms; in these an infectious element (unless the underlying lues be so considered) is absent. In Bryan's case, too, no foci of infection were apparent. So that the infectious theory has its flaws. Venous stasis alone will not suffice to produce an osteo-arthritis. Either stasis or infection or both combined may be found in most case reports. Bryan's showed neither. There was stasis, it is true, but a strangely scat-

tered and localized stasis very difficult to explain. There was generalized lymphostatic edema of all the four limbs; the colon was edematous, but not the small gut; nor was there more than a very little free fluid in the belly, and very little, too, in the pleurae. This peculiar localization cannot be accounted for by a block of the great veins at the heart or in the mediastinum. So that the theory of a venous stasis is also insufficient to explain every case.

The cause of this patient's lymphatic block remains a puzzle, but, whatever the cause may be, lymphatic obstruction may have something to do with the production of the periosteal deposits and the clubbing of the fingers and toes.

Douglas Campbell, in the *British Medical Journal* for January 24, 1924, illustrated sections of club-fingers in a case of osteoarthropathy following cancer of the lung. They showed nothing but edema without osseous changes; the long bones, however, were covered with typical periosteal deposits. Periosteal deposits similar to those of osteoarthropathy are also common in elephantastic limbs. Campbell considers lymphatic obstruction as the etiological factor underlying secondary osteoarthropathy. He attributes the edema to imperfect oxygenation, whatever the cause of this imperfection may be, and thus explains the clubbing described after disease of the liver and other extrathoracic organs, which may also lead to imperfect oxygenation.

It seems to me that the theory of a lymphostatic origin—possibly an infectious one—has more to offer in many ways than the theories of "toxemia" and venous stasis which have hitherto been advanced.

Dr. Bryan's case is of uncommon interest and adds strength to this theory of Campbell's.

W. R. P. CLARK, M. D. (516 Sutter Street, San Francisco)—This case of secondary hypertrophic osteoarthropathy following metabolic sarcoma of the lung, reported by Doctor Lloyd Bryan and discussed by Doctor Leo Eloesser, has been of unusual interest to me from several points of view:

1. On account of the question of the etiology of osteoarthropathy, and this point has been well considered by Bryan and Eloesser.

2. On account of the rapidity of the appearance of osteoarthropathy. I think many of us have been inclined to think of this condition as being of slow development and when present, in tuberculosis or heart disease, as indicating a primary disease of long duration, whereas in tuberculosis it is often a matter of months rather than of years.

3. On account of the malignancy of the lung. So many cases of malignancy of the lung, either primary or metastatic, have come to my notice during the past two or three years, that I have been impressed with the fact that one should keep constantly in mind this condition when making a differential diagnosis of chest pathology.

4. And, lastly, on account of the failure of x-ray therapy. All of us have hoped that, with the advent of deep x-ray therapy, a cure for malignancy might have been found, but this is one more case that has failed to respond. I do not wish to be misunderstood, however; x-ray therapy, I believe, still has its place in the treatment of malignancy of the lung, for, even if the progress of the disease may not be prevented, oftentimes some of the symptoms may be greatly ameliorated.

Training the Mind to Rest—Some men, when not working at routine, will close their minds like books. Like steamship captains they will signal "Finished with the engines" and let a dynamo become inert. For them there are no Elysian fields of intellectual pastime, no exaltation in thought of knowledge gained or service rendered. They work and they cease working; there is no eager turning to new fields to browse in. They do not think while smoking; they simply smoke, like cloud-compelling Jupiters, as Dean Briggs has characterized one class of undergraduates. Such of us may dream, but we do not wake and carry out our dreams.—*The Boston Medical and Surgical Journal*, Editorial.

SPINAL ANESTHESIA IN UROLOGY

By J. C. NEGLEY, M. D., Los Angeles

*Reports over five thousand patients without a death.
Success means careful attention to all details.*

IMPORTANT DISCUSSIONS by R. L. Rigdon, San Francisco; Miley B. Wesson, San Francisco; Arthur B. Cecil, Los Angeles; Granville MacGowan, Los Angeles.

IN PRESENTING this paper, I wish to tabulate our experiences, impressions and conclusions regarding spinal anesthesia at the Los Angeles General Hospital. It was introduced at this institution over twenty years ago by Dr. Granville MacGowan, and since that time it has been used in approximately 5500 cases for either operation or cystoscopic examination in difficult cases. Doctor MacGowan first used cocain, grain $\frac{1}{4}$, dissolved in 2 cc. of water. This method proved unsatisfactory, in that syncope and respiratory difficulty were frequent, and this drug had to be abandoned. Stovain was next tried and this drug also proved to be dangerous. Two cases in which stovain was used, Doctor MacGowan reports a localized necrosis of the external surface of the calf of the legs and heels, limited to the skin and down to but not through the deep fascia. This necrosis seemed to follow the distribution of the peroneal nerves. Finally, he began the use of tropacocain, which he has found most satisfactory and which he still uses. During the last six years novocain in 1 or 2 grain doses has been the drug most commonly used at this institution. Either drug may be dissolved in sterile distilled water or in the spinal fluid itself. There is very little difference in the toxicity of novocain and tropacocain.

TECHNIC OF ADMINISTRATION

The drug to be used is placed in a small glass vial of 1 or 2 cc. capacity and sterilized dry at a temperature of 90 to 100 C. for one hour. The already prepared ampules of the dry drug put out by the drug firms answer the purpose just as well, but are too expensive in large amounts. Using a 5 or 10 cc. Luer, with a 24 gauge needle loaded with one-half per cent novocain, a wheel is made over the third or fourth lumbar interspace directly in the center. The small needle is then removed from the Luer, and one two inches long, gauge 21 or 22, is substituted. With this, one can infiltrate the fascia and muscles clear down to the dura, after which the puncture itself will be practically painless. A Quincke needle of about 22 gauge is then used for the puncture. The dry crystals may be dissolved in the spinal fluid, if preferred, or may have been previously dissolved in sterile distilled water. This seems to be a matter of no importance. About 10 cc. of the spinal fluid is drawn up into the syringe and reinjected, repeating this procedure (four or more times) so that proper diffusion of the drug in the subdural space will be accomplished. In such a large teaching institution, where the administration of the anesthetics must be co-operated in by a number of individuals, the anesthesia is often insufficient to perform supra-pubic operations painlessly, perhaps in about 20 per cent of the cases. However, in those cases where the procedure is in the hands of one person thoroughly trained and skilled in its use, the percentage of failures of complete anesthe-

sia falls to 4 per cent, or even less. In the event of partial anesthesia, a surprisingly small amount of ether or nitrous oxide will complete the anesthesia. Absorption of the drug is rapid, and if the anesthesia is going to be successful, one can begin the operation in five or six minutes, and probably more than 90 per cent of the drug is absorbed in ten minutes. After ten or fifteen minutes, the patient can be put in the Trendelenburg position with safety. In fact, like the toxic effects of general anesthesia, the patient will respond much better in this position than in a recumbent one.

The most marked and noticeable effects of spinal anesthesia is the rapid drop in blood pressure and a change in type of respiration due to anemia of the brain and the reflex started in the solar plexus. The pulse beat becomes feeble and slower, and almost imperceptible at times. These effects are terrifying, but the real adjustment of both respiration and circulation is almost as rapid as their onset. The patient is apt to have nausea and vomiting at this time, which is not prolonged for any great length of time.

SELECTION OF CASES FOR THIS FORM OF ANESTHESIA

It is particularly useful in the operation of suprapubic prostatectomy where we have feeble old men with chronic bronchitis and emphysema, damaged kidneys, and a heart that is susceptible to strain. Following operation, there is often no nausea or vomiting, and when there is gastric distress it usually subsides much more quickly than that from a general anesthetic. This is a great advantage, since most of these patients need an abundance of fluids, and also lessens the danger of hernia from an operation in which a necessarily large hiatus in the aponeurosis of the rectus muscle is left. (At this institution, the greatest number of patients who receive spinal anesthesia occur in the rectal clinic. Here anesthesia is nearly always successful, whereas it doesn't always reach the suprapubic region.) Hemorrhage may occasionally follow prostatectomy with this anesthetic, if one is not careful to use a Pilcher bag, or pack the bladder. There may seem to be no hemorrhage when the operation is completed, but as the blood pressure returns to normal, bleeding may set in. Headaches follow spinal anesthesia in a smaller percentage of cases than from simple lumbar puncture for this reason: In most of the cases operated upon the patient is kept in a recumbent position for at least many days, and when a simple lumbar puncture is done he is apt to be up and about after the first or second day. Practically, the only cases that have severe headaches are for very minor surgical procedures or examinations where the patient is allowed to get up or sit up at a very early date following the operation.

DISADVANTAGES

It is not a method to be used with satisfaction by anyone not thoroughly familiar with the technique, even to the slightest detail. Such a rapid and marked fall of blood pressure acts as a profound shock to some of these old men with greatly lowered resistance. Patients who are neurotic sometimes become so restless and move about so much as to interfere materially with the operation. The head-

aches that sometimes follow are a detriment, in that they retard convalescence from the distress and lack of sleep.

Once given, the anesthetic cannot be stopped except by reinsertion of the needle and withdrawal of spinal fluid, which is a dangerous and awkward procedure in a patient with shock.

It cannot be given in graduated amounts to suit the different stages of the operation as can a general anesthetic. In cases that do not get anesthesia, the operation must be postponed or a general anesthetic given, which is not always possible.

Spinal anesthesia in this series of cases seems to have been the best possible anesthetic and, in that type of cases before mentioned, is far superior to the general anesthetics. Time alone will tell whether it will be supplanted by sacral, parasacral, and other methods of regional anesthesia.

219 West Seventh Street.

DISCUSSION

R. L. RIGDON, M. D. (291 Geary street, San Francisco)—It has seemed best to make this discussion in the first person, rather than to review the experience of others. These records are open and can be read as well, or better, in other reports than mine, and each surgeon can formulate his own conclusions.

Many years ago I began the employment of intradural injections, and for a time I was very enthusiastic over my results. Then disaster came my way, and a patient died on the table. Reluctantly I took up general anesthesia. After a number of years, such glowing reports were made from clinics that had continued the use of spinal anesthesia that I found myself once more impelled to resume that method. This was during the war. Again I was delighted, but having lost one patient before I was rather apprehensive; in fact, I was a bit "gun shy," as it were, and when I was operating and I would notice the patient's face taking on an ashy hue, I would become very much alarmed and would pass a very uncomfortable fifteen or twenty minutes, wondering if the patient would ever come back. In the meantime, the administration of gas and oxygen as an anesthetic had become so satisfactory in skillful hands, that I felt myself almost compelled to use that method. For a number of years this has been the only anesthetic I have used, except now and then ether. The patients do very well, but of course there are occasional symptoms of nausea, vomiting, general malaise, and perhaps a tendency to freer bleeding. Now comes this report which shows a remarkable record of successes and no fatalities.

Perhaps I may once more revert to the spinal needle and novocain. If so, I hope I may be able to control my disposition to sweat, when the symptoms of collapse come.

MILEY B. WESSON, M. D. (Flood Building, San Francisco)—In this very interesting and concise paper the author has clearly brought out that the success and safety of spinal anesthesia is the user rather than the method; if it is dangerous it is because it is used without full understanding or recourse to necessary antidotal safeguards; if it is ineffective, the technique has not been acquired; and if there are frequent post-operative complications, it is because something has been done that should not have been done.

Intra- and extra-dural nerve blocking are new procedures, spinal anesthesia having been introduced by Bier in 1904 and sacral anaesthesia by Stoeckel in 1909, consequently reports are meager. Statistics are worthless unless there is a large volume to deal with. Bromfield, in a recent study of 2,171,461 anesthesia administrations, found the mortality from ether to be 1 in 8010, and in spinal analgesia 1 in 515. Babcock, in a series of 15,000 spinal inductions, found a mortality of 1 in 10,000 in selected cases, and 1 in 500 in unselected; while Steel had 3 deaths in 5000 cases in a period of fourteen years, none occurring during the last five years. In analyzing statistics, one is impressed with the facts that the unto-

ward effects occur during the first years of use and before the operator has acquired his technique.

In 1912, following an epidemic of cerebrospinal meningitis, I published a series of 800 uncomplicated lumbar punctures, and I found at that time that the use of serum by the incompetent caused about the same complications as Dr. Negley has noted.

We have all been trained with the idea that little skill is required to give an anesthetic, so such duties fall to the junior intern or the nurse. When such an assistant is given a Quincke needle and a book of instructions, someone's series of a hundred cases or less is going to show complications ranging from paralysis to exitus. Since the reports of complications in the literature generally come from such small series of cases, the question naturally arises whether the method is at fault or personal incompetence should be blamed. Sacral anesthesia has proven very satisfactory at the Mayo Clinic, because Labat was brought from Pauchet's Clinic in Paris to teach its use. Intra- and extradural nerve-blocking is a delicate procedure, requiring more skill than the suprapubic removal of a prostate, and the anesthetist should not only be a surgeon, but have an intimate and an exact knowledge of physiology and pharmacology.

Any operation whose technique cannot be quickly mastered by the average surgeon should not be used by any but trained specialists. Spinal anesthesia administered by experts to properly selected cases is efficient and harmless, but in the hands of amateurs is still pregnant with dangerous possibilities, hence I do not feel that its general use should as yet be encouraged.

ARTHUR B. CECIL, M. D. (Pacific Mutual Building, Los Angeles)—It gives me great pleasure to discuss Dr. Negley's article on spinal anesthesia in urology. He has made a contribution which is notable not only for giving exact methods of technique, but for his unbiased discussion of a subject with which he is thoroughly familiar. There are undoubtedly cases in urology where general anesthesia is to be avoided, and I take it that Dr. Negley would more or less limit the use of spinal anesthesia to these instances.

Personally, I do not believe that as a routine spinal anesthesia will ever replace general anesthesia. I believe that, all in all, it is more dangerous; that one would have more accidents than would be the case where general anesthesia was properly administered. Unconsciousness of itself should never be a deciding factor. I am not at all sure that the state of unconsciousness of one's patient does not many times result in a better surgical procedure than one could carry out were the patient conscious.

So far as I have been able to determine, unless there were definite indications for local or spinal anesthesia, I would much prefer to have the urological case under a general anesthetic properly administered; and yet in making this choice I realize that very few people have the ability to carry out spinal anesthesia with the degree of success of which Dr. Negley is capable.

GRANVILLE MACGOWAN, M. D. (Brack Shops Building, Los Angeles)—In examining the discussions of Dr. Negley's paper by Drs. Rigdon, Wesson, and Cecil, I am reminded of the Asiatic proverb that "Most of the evils we fear never happen." All the dangers which are conjured up by suspicious and timid souls, as applying to spinal anesthesia were thought of by me and resulted in my most bitter opposition to this method of producing analgesia during the first year after the method had been proposed and its possibility demonstrated. An accidental circumstance led me to overcome my prejudice and use it in a case where any method of anesthesia involved more danger than the operation itself. The agent at this time was cocaine, and it was with much fear that I used it. The results were so satisfactory and so astounding to me that, with great caution, I occasionally used spinal anesthesia for perhaps a year. Although no fatalities occurred in my practice, there were sufficient that arose throughout the world to make its dangers seem very real. Then tropo-cocaine with a toxicity enormously less than cocaine was discovered and introduced for use in spinal anesthesia. I became one of its users, and it has been my favorite method of obtaining anesthesia in my cases of genito-urinary surgery in which the circulatory or respiratory condition was unfavorable for the use of a general anesthetic, or when there existed a morbid fear of being rendered unconscious, or when it was desirable that the person on

whom the operation was being performed should have the muscles of the lower abdomen and of the perineum entirely relaxed during the period of operation. I have never had any fatality, nor any serious trouble arising from this anesthetic. During the same period of time, where from reasons of prejudice, or as during the war when tropo-cocaine was for a time unobtainable, a general anesthesia—gas oxygen or ether—had to be administered, I have often experienced very real difficulty and much trouble and interruption of the operation to restore or revive the patient.

I do not believe that routine spinal anesthesia will ever replace general anesthesia, not because it is more dangerous, but because it seems to require a considerable amount of mechanical skill and judgment that the average surgeon does not possess and will not learn.

By using a small and delicate needle for the spinal puncture, there is, in my opinion, no chance for any mechanical injury to the cord if the surgeon does not possess the idea that the only way of obtaining access to the subarachnoid space is by means of rape of the spinal column. In performing lumbar puncture, either for diagnosis or for anesthesia, I teach the humane method of anesthetizing the skin and the deeper tissues down to the dura with a half per cent solution of novocaine before inserting the spinal needle.

The headache which one occasionally sees follow spinal anesthesia is not due to the drug, because it very frequently follows a simple spinal puncture where the individual is allowed to be up and about too soon. The fact that the nature of the operations upon the uro-genital organs in which I use spinal anesthesia requires a long sojourn in bed is usually sufficient prophylaxis against these headaches. It is never necessary to have the patient out of bed early. The trail of stinking urine marking their progress is, to my mind, an evidence of cruelty and indifference to comfort upon the part of the operator.

There is another point upon which I wish to dwell, which is, that the relaxation obtained by spinal anesthesia avoids the necessity for the extremely rapid operative procedures which are regarded by so many as absolutely necessary in genito-urinary surgical work, a rather nefarious belief, founded entirely upon the evil effects which are known to result from a prolonged anesthetic. Under a spinal anesthetic, plenty of time can be taken for deliberative movements and completion of the operation, which should be finished when once commenced.

Individually, I have been very glad that such an agent existed, not only on account of the many cases of bad risks which I have been able to conduct to a favorable conclusion, but also on my own account, because for many years I have been obliged to operate with one arm, the subject of a traumatic neuritis which never has been during the whole period without pain, and the muscular relaxation of the patient has saved me from struggling with him, as so commonly happens in supra-pubic manipulations inside of the bladder and in perineal operations where the patient does not lie quiet under a general anesthesia conducted by timorous or unskillful anaesthetists.

DOCTOR NEGLEY (closing)—Doctor MacGowan, in his masterful discussion of this paper, has left very little for me to say, as he has answered both Dr. Rigdon and Dr. Cecil in their attitude toward this method of anesthesia.

Dr. Wesson's concluding remarks regarding the use of spinal anesthesia cover my attitude exactly, except that I think surgeons in general, and urologists in particular, should learn the technique absolutely and use it more frequently.

Mails Closed to "Cures"—The Postoffice Department has issued "fraud orders" against two alleged tuberculosis cures recently, and they are getting quite busy with certain other classes of "fakirs" who use the mails to exploit the sick. One of the tuberculosis "cures" fooled a lot of newspapers by sending out their "news" stories as quotations from Dr. X, quoted as "a prominent doctor of —." The doctor referred to proved to be an osteopath. "Doctor — of California," said by the newspaper stories to be a "national authority" on tuberculosis, was given front-page prominence for another "cure" for tuberculosis. Investigation showed that no such doctor lived in California.

A STUDY OF TWENTY-ONE CONSECUTIVE AMBULATORY BACK INJURIES, WITH SPECIAL REFERENCE TO FRACTURES OF THE SPINE.

By H. W. SPIERS, *Los Angeles*

The frequency of bone injury to the spine.

The infrequency of malingering.

The necessity of careful clinical study of the injured back.

The value of stereoscopic and lateral x-ray examination of the suspected area, and above it.

DISCUSSION by E. W. Cleary, *San Francisco*; D. I. Aller, *Fresno*; C. E. Early, *Los Angeles*.

FROM May 1, 1922, to October 1, 1923, I examined fifty-five back injuries. All were ambulatory patients. A large majority were men. All but a few had been seen and studied by from one to several surgeons. In the main, their diagnoses were not very definite. Of the fifty-five patients, twenty-one were found to have a definite spine injury, as shown by the x-ray examination. It is these twenty-one with bony injury that I wish to discuss.

About half of them were referred by physicians; the remainder were referred by the Industrial Accident Commission. Thus, the man with the injured back is frequently seen by the orthopedic surgeon as referee. Some of these individuals are keen type of men, but the most of them are of the class among whom one would hardly expect a clever malingerer. Of the series examined, none was proven a definite malingerer. That a good many exaggerated their symptoms I am certain, but all had some basis for their complaint. A number showed no signs definite enough to warrant a diagnosis of serious injury. In others, whose previous diagnosis had been "neurosis" or "railroad spine," I was able to demonstrate definite bone injury.

A careful history, an orderly examination, including intelligent x-ray study, goes a long way toward getting to the root of the trouble.

In the history, the type and manner of the injury should be given consideration. The distance of a fall may not be of as much importance as of the way in which the individual landed or of the object upon which he landed. I found it fairly common to find a crush fracture of a body of the lower dorsal or upper lumbar spine when the fall was such as to cause the man to land on his upper back and shoulders. This is reasonable when one considers that a bow breaks most frequently near its middle, not at its end. Fractures of muscular violence are not unusual. The individual in the bent-forward position lifting a heavy object, who slips or is suddenly forced to carry more than his muscles are mechanically able, frequently fractures parts of his spine. Fractures of the transverse processes are frequently from muscular violence. Usually there has been a rotary violence also. The articulating facets occasionally give way under similar violence, in my opinion.

An orderly examination includes an inspection of

the entire back, with the patient entirely stripped. The position and attitude of the head and shoulders should be noted. The normal curves of the spine and their variations if any, should be checked up. The weight line of the body, both lateral and antero-posterior, is of importance. A study of the function of each of the segments of the spine should be made. It is to be remembered that the greater part of the motion of the spine takes place in the lumbar region. Here forward, lateral and backward movements, as well as rotations, have the widest range. Limitation of movement in this region is much more easily demonstrated than in the upper and middorsal segments, but even there careful observation will demonstrate it if present. It is my custom to palpitate the spinous processes and the area lateral to them throughout the entire spine. Deep pressure over the injured vertebra is liable to produce marked subjective symptoms. If there is an injury to the transverse process, as one would expect, active movements which involve the muscle groups attached will produce symptoms, while passive movements will usually be painless. An injury to the articulating facet localizes itself if a study of the signs, symptoms, and function of the segment involved is made. I feel that injury to these facets is more frequent than is generally recognized. Rotary, muscular or direct violence, if the leverage is right, will frequently result in fracture. Fractures of the body of the vertebrae may give symptoms similar to any of the other types of fractures. I think it is only just to say that there are crushing injuries to the bodies of the vertebrae which cannot be demonstrated early, but which on later examination show the definite wedge shape that is so characteristic. The probable explanation is that the body was damaged and its structural strength impaired, giving way gradually under the superimposed weight of the trunk.

Stereoscopic x-rays are of much more value in demonstrating the lesser bony injuries to the spine than the flat plates. Lateral views are essential in the study of the spine, and we are only just beginning to appreciate the value of these. All examinations were made with the aid of the Bucky diaphragm. Certain films which had previously been taken of these patients were seen. Some were simply poor plates, which, of course, eliminate good diagnosis. Others were not well localized, the region of the injury had not been included, and many where the injuries were included were flat plates in which the injury of the lesser processes could not be demonstrated. A good lateral view of the spine until recently has been a difficult thing to secure. Many of them are altogether inadequate. It is my experience that one is likely to localize the injury lower than it actually is. One must keep in mind that referred symptoms radiate downward in all spine injuries. In other words, have your x-ray study include several vertebrae higher than the supposed injury, as indicated by the findings. A mistake to avoid is trying to cover too large an area in the individual film. After one's study has been carefully made, the region of the injury can usually be indicated to the radiographer and a clearer knowledge of the bony structure thereby obtained.

Some of the outstanding clinical facts noted in

this series were: the importance of muscle spasm, the value of studying with the range of motion of all segments of the spine, and the comparative rarity of definite evidences of nerve lesions. It is my opinion that definite muscle spasm means definite pathology. An injury to the spine almost invariably limits the motion of the segments to some degree. The point of maximum subjective symptoms during palpation is usually taken as the clue to the segment that should be most thoroughly studied. It is not difficult to make a diagnosis of a fractured spine if one has evidences of definite cord or root lesion, or a good lateral view and sees a wedge-shaped vertebra. It is more difficult, however, to account for some of these injured spines that have the lesser bony processes only involved. These usually have at most only referred pain as evidences of nerve disturbance and can be demonstrated only by the most clear-cut films and painstaking study.

Regarding malingerers: A study of the table of cases shows that, out of twenty-one, six were definitely said to be malingerers. Of the remaining fifteen, practically all were thought to be exaggerating their symptoms. I am definitely of the opinion that we, as surgeons, have made many greivous mistakes in our diagnosis of the neurotic spine. Since x-rays show that the lesser processes of the spine are frequently damaged and that compression fractures are not at all infrequent, due even to muscular violence, one must admit that this proposition has a great deal of basis of fact. It does not seem reasonable to me that an individual whose earning capacity is far greater while at work than when laying off, receiving insurance or individual compensations, might, for some imaginary or minor disability, greatly exaggerate his symptoms.

The points I wish to bring out are:

1. The frequency of bony injury to the spine.
2. The infrequency of malingering.
3. The necessity of careful clinical study of the injured back.
4. The value of stereoscopic and lateral x-ray examination of the suspected area and above it.

No. 1—M. V., 28 years old. Injured April 6, 1921. He was injured by lifting a weight of about fifty pounds in an awkward stooped position. Examined twelve months later. Previous diagnosis, sprain of the low back. He complained of low back pain, which radiates down the left leg. The pain is relieved by rest, and increased by exertion. Examination showed limitation of movement and muscle spasm in the low back. X-ray findings show a rotary luxation of the fifth lumbar vertebra on the sacrum, and a fracture of the right sacral articulating facet; also impingement of the left transverse process of the fifth lumbar vertebra on the iliac crest.

No. 2—A. R. P., 54 years old. Injured August 10, 1921, by falling from a building a distance of fifteen feet, landing on his upper back. Examined nine months later. Previous diagnosis, neurosis. He complained of constant pain in the low back, which radiated downward to the region of the left knee; also pain in the lower abdomen. There was evident limitation of movement in all directions in the region of the upper lumbar and lower dorsal vertebrae and marked muscle spasm. X-ray examination showed a compression fracture of the bodies of the second, third, and fourth lumbar vertebrae with bony overgrowths.

No. 3—J. C., 69 years old. Injured December 7, 1921, by being struck by an electric trolley car, suffering a broken jaw, broken ribs, and injured back. Examined ten months later. Previous diagnosis, as regards the back, was neurosis. He complained of backache on standing

and walking. Examination showed marked muscle spasm throughout the entire low dorsal and lumbar spine, with marked limitation of flexions in the lumbar regions. X-ray findings showed a fracture of the transverse processes of the second and third lumbar vertebrae.

No. 4—C. O., 38 years old. Injured September 25, 1922, by being crushed by a mass of falling dirt. Examined one month later. Previous diagnosis, contusion and sprain of the back. He complained of pains in the left hip, thigh, and lower leg. There was marked muscle spasm in the low lumbar region and slight limitation of movement in that region. The x-ray findings showed a fracture of the transverse process of the fifth lumbar vertebra.

No. 5—H. E. B., 33 years of age. Injured November 30, 1921, by an automobile body falling on him, causing numerous abrasions and injury to the cervical spine. Examination made one year later. His complaint then was stiffness in the cervical spine, sensitiveness and discomfort on movement of the spine which radiated down the left arm, and to a less extent down the right arm. Previous diagnosis, hypertrophic arthritis. Examination showed limitation of motion in the cervical spine. X-ray examination showed a crush fracture of the bodies of the fourth and fifth cervical vertebrae, with slight backward displacement of the fifth.

No. 6—B. M. B., 54 years of age. Injured August 29, 1922. He fell twelve feet from a scaffolding, striking on his right shoulder and head. Examined three months later. Previous diagnosis, concussion of the brain and sprain of the neck. His complaint now is of constant pain and stiffness of the neck and shoulder. Examination showed marked limitation of movement in the cervical spine below the second cervical, with considerable atrophy of the muscles of the left shoulder. X-ray findings show a compression fracture of the bodies of the fifth and sixth cervical vertebrae and sprain fracture of the body of the fourth and fracture of the superior posterior angle of the right scapula.

No. 7—A. B., 35 years old. Injured March 2, 1922, by being caught in the door of a cotton press, and his shoulders and back pressed violently together. Examined nine months later. Previous diagnosis, neurosis. He complained of pain in the back between the shoulders. This pain radiated forward, greatly increased by lifting and bending. There is bilateral muscle spasm in the mid-dorsal region, and slight limitation of motion in the dorsal spine. X-ray examination shows a rotary disturbance between the sixth and seventh dorsal vertebrae. The descending articulating facet on the right side showed evidences of an old fracture.

No. 8—C. E. P., 64 years old. Thirty-five years prior to examination he fell and was laid up for three months. He gradually improved and returned to work. Has had no particular difficulty until seven months ago, when he fell and struck a step and had a return of his symptoms. Examined April 17, 1923. Previous diagnosis not made. He had been treated by manipulations, with exaggeration of symptoms. The objective symptoms were marked limitation of movements throughout the entire lower dorsal and lumbar spine and muscle spasm. The x-rays show an old fracture of the bodies of the eleventh and twelfth dorsal and first and second lumbar vertebrae, with proliferative arthritis of the first and second lumbar vertebrae. It is felt that, in all probabilities, that the original injury was thirty-five years ago, and that the present injury was a fracture of the fusion between the first and second lumbar vertebrae which the x-rays seemed to demonstrate.

No. 9—A. T. H. Injured February 21, 1923. Examined two months later. Twenty years previous he had a serious injury in a wreck in which his spine was hurt. He was laid up for many months. This injury took place while lifting a heavy weight. No previous diagnosis had been made. He complained, at time of examination, of pain in the middorsal region, which extends downward and forward. Herpes zoster developed, but did not relieve the pain. The scars of the rash were present and marked muscle spasm in the dorsal region. The x-rays showed a compressed fracture of the fifth, sixth, and seventh dorsal vertebrae. There was marked callous formation.

No. 10—H. J. S., 60 years old. Injured April 13, 1923,

in a cave-in of earth. Examined two months later. Previous diagnosis, back strain. He complained of pain in the lower back when stooping or lifting. If he was quiet he was fairly comfortable. The objective symptoms showed marked muscle spasm. There was a structural curve of the spine and limitation of all movements of the lumbar spine. The x-ray showed a sprain fracture of the body of the third lumbar vertebra and a fracture of a superior articulating facet of the fourth lumbar vertebra.

No. 11—J. R., 55 years of age. Injured January 29, 1923, by having a truss fall on him, striking him in the back. Examination made five months later. Previous diagnosis, hypertrophic arthritis. He complained of chronic pain in the low back. The pain was increased by exercise and movement. The objective symptoms were limitation of motion of the entire spine and muscle spasm in the same region. X-ray examination showed a separation of the fused hypertrophic process on the right side between the third and fourth lumbar vertebrae.

No. 12—R. B., 33 years of age. Injured January 20, 1923, when he fell from a scaffolding, striking on his back on a plank. Examined six months later. He complained of backache and headache. The lower dorsal and lumbar spine showed marked muscle spasm. There is a very marked exaggeration of the lumbar lordosis. Previous diagnosis, neurosis. X-rays show a crush fracture of the bodies of the eighth, ninth, and tenth dorsal vertebrae.

No. 13—J. C. G., 34 years of age. Injured May 19, 1923. While lifting a kettle of hot fat weighing about ninety pounds he slipped, and in his effort to throw the fat away from him so as not to scald himself he injured his back. Examined two months later. He complained of pain in the low back and right hip, and of discomfort on forward bending and lifting. Examination showed marked muscle spasm throughout the lumbar region. There was a structural curve of the spine which seemed to be a left dorsal, right lumbar curve. All movements of the lower spine were guarded. X-ray examination showed a fracture of the transverse process of the third lumbar vertebra and of the vertical articulating facet of this same vertebra on the same side.

No. 14—L. W. M., 39 years old. First injured July 9, 1921. At that time he was struck by a freight elevator door while he was standing in the forward flexed position. He was disabled for a number of weeks, but gradually got around, although for a period of one year he complained of back pains. He recovered, however, until he was doing a normal day's work. On March 21, 1923, while in a similar flexed position he was hit in the same region by a truck. He had a similar pain as in the previous injury, and since that time had been unable to work. Examined four months after the second injury. He complained of pain in the low back. The previous diagnosis in each case had been sprain. Objectively, his back showed marked muscle spasm from the middorsal region to the sacral region. The x-ray examination showed a vertical fracture through the lamina of the fourth lumbar vertebra to the right of the spinous process; also a healed similar injury to the fifth lumbar vertebra. In this case it was our opinion that the fractures occurred at the time of the original injury, but the condition was reopened by the second.

No. 15—F. R., 49 years of age. Injured July 9, 1923, by falling into a hopper, with one leg extended and the other flexed, landing on his back on a hard, projecting pipe. Examined two weeks later. Examination showed marked limitation of flexions and extensions of the lower spine. The lumbar and low dorsal muscles were in marked spasm. Previous diagnosis, sprain. X-ray examination showed a crush fracture of the body of the first lumbar, with fracture of the inferior articulating facet of the third on the right side; also a fracture of the lamina on the right side of the second lumbar vertebra.

No. 16—H. H. P., 41 years of age. Injured December, 1922, while endeavoring, with an assistant, to lift a crossbar of steel weighing about three hundred pounds. His assistant slipped, throwing the entire weight on him. Examined nine months later. Previous diagnosis, sacro-iliac slip. He had been manipulated several times—last time under ether—following which he was very much worse. Objectively, his spine showed an extreme list to the right, exaggerated lumbar lordosis and marked muscle

spasm from the sixth dorsal vertebra downward and limitation of motion in the lumbar spine. X-ray examination showed an old fracture of the transverse processes of the fourth lumbar vertebra.

No. 17—W. A. C., 28 years old. Injured in 1918 from a fall from an airplane. Examined August 3, 1922. He complained of chronic low back pain on the left side which had been constant since injury. Objectively, there was muscle spasm and limitation of motion in the lumbar region. Previous diagnosis has been neurosis. He had been treated for a long period on this basis in the army hospital. X-rays showed a compression fracture of the first lumbar vertebra and lesser evidences of a compression fracture of the fifth lumbar vertebra.

No. 18—J. P. K., 34 years of age. Injured in a motor-car accident four years ago. Examination made April 6, 1923. He complained of backache intermittently since his injury. Examination showed muscle spasm and limitation of lateral movements of the spine. Previous diagnosis, strain. X-ray findings showed an old compressed fracture of the first lumbar vertebra.

No. 19—J. C. H., 84 years old. Injured March 28, 1923, by falling in the bathroom. He fell in such a way that he was doubled up between the wall and the tub. Examined the next day. He complained of acute pain in the low back. There was marked muscle spasm throughout the entire dorsal spine. He was unable to lift himself up or stand except with great difficulty. The spine sagged laterally, and there was a beginning kyphus. X-ray examination showed a crush fracture of the bodies of the first and second lumbar vertebra.

No. 20—J. D., 30 years old. Injured May 5, 1923, by being struck in the back by a crowbar. Examined four months later. Examination showed marked muscle spasm and limitation of motion of the back. He complained of back pain. Previous diagnosis, sacro-iliac strain. X-ray examination showed a forward luxation of the fifth lumbar vertebra on the sacrum.

No. 21—J. L. S., 33 years old. Injured November 12, 1922, by muscular violence, lifting with a severe twist. Examined in consultation one week later. Diagnosis of fracture of superior articulating facet of the fifth lumbar was made. Two days later was seen by another surgeon, who disputed diagnosis and manipulated the spine without result. Again seen three months later. X-rays showed definite callous development about the fractured facet.

614 Westlake Professional Building.

DISCUSSION

E. W. CLEARY, M.D. (177 Post Street, San Francisco)—Dr. Spiers has brought to our attention a number of points of major significance in investigating back injuries.

My experience has led me to conclude that actual malingering is rare, but exaggeration quite common as a complication of back injuries. Carelessness and lack of precision in the examination of back injuries have contributed to bring about a bad situation. The individual who desires to exploit someone through the compensation law has come to believe that he may readily do so by claiming disability associated with a lame back.

Definite physical signs are, I believe, always present in instances of disabling back injury. It is up to every surgeon who assumes the responsibility of passing opinion upon such a patient to make sufficiently thorough investigation, including x-ray examination to discover the physical signs present. In the absence of physical signs, I believe, that symptoms alone can safely be accepted as proof of disability only in instances where there is an unquestionable history of actual severe and unusual stress having been brought upon the spinal column.

I have not yet seen a compression fracture of a vertebra which I am sure was due to a lifting strain. I have seen several such fractures, which had been attributed to lifting strain, but in every instance careful inquiry discovered a history of a previous severe fall or crushing accident, which, in my opinion, accounted for the vertebral distortion credited to the more recent lifting strain. I would like to ask Dr. Spiers how many compression fractures of vertebrae he has seen which were unquestionably the result of lifting strain.

D. I. ALLER, M.D. (Mattei Building, Fresno)—I have

read with interest Doctor Spiers' excellent paper on fractures of the spine, and I find that he has stressed many points upon which I insist in all severely traumatized backs.

In all spine injuries one never is too careful or exacting in determining the exact nature of the fall, crush, or body position at time of accident.

In my experience, both as to private cases, industrial cases and in work at the General Hospital, there has always been clinical evidence of sufficient moment to warrant a thorough investigation in the x-ray laboratory.

The anomalies of the fifth lumbar vertebra are in some instances apt to be misleading, and may result in an incorrect diagnosis.

It has never been my privilege to see a compression fracture of a vertebra due to a lifting strain; however, do not understand that I question such a possibility in spines weakened from disease or previous injury.

C. E. EARLY, M. D. (Golden State Hospital, Los Angeles)—This paper presents several interesting points. The more proficient we become in the examination of injuries and the interpretation of x-rays, the less malingering we see. Exaggeration of existing symptoms is not uncommon. This is especially noted in back injuries, and is due to a faulty psychological impression often induced by the surgeon. The surgeon treating back injuries should explain, in detail, the condition to his patient, giving him as good a prognosis as possible. A fractured vertebra should never be called a "broken back." Correct mental stimulation is good therapy in back injuries.

Careful, painstaking study and examination with the clothing entirely removed is essential. Examine the entire body. Focal infections and pre-existing diseases are oftentimes an important factor in diagnosis, treatment and prognosis. Rectal examination should always be made. I believe that spinal fractures will show definitely localized symptoms. When my patient is unable to localize his pain and rubs his hand over a considerable area of his back, I look upon the case with suspicion. Careful x-ray study is of greatest importance. Stereoscopic and lateral views should be had. It is unfortunate that we are unable to secure lateral views of the upper dorsals, but it is seldom that a compression or crushed fracture occurs in that region.

I have never seen a crushed fracture due to strain, nor do I recall having seen a fractured transverse process due entirely to strain unless it were a very small avulsed chip from the tip of the process. I do not believe a healthy vertebral body was ever fractured entirely by straining. Fractured transverse processes do not cause prolonged disability. The disability ordinarily does not exceed sixty days. In only two cases have I removed fractured transverse processes for continued pain. If I examined a painful back several months after injury and found only fractured transverse processes, I would conclude that there was other cause for the pain.

Impingement of the transverse processes of the fifth lumbar on the iliac crests is more theoretical than real. It seldom if ever occurs unless the process is malformed. Examine a skeleton and note the distance between the process and the ilium; also note the downward and backward curve of the iliac crest. Fractures through the articular processes and facets are rare, but probably occur in many cases where they are not demonstrable by the x-ray.

The percentage of cases that show nerve symptoms is small, unless the crushing has been severe. In these cases the nerve symptoms generally follow immediately upon the injury. In a few cases of compression of the body of a dorsal vertebra I have found pain due to pressure on the nerve root referred around the rib to the front of the chest. Fractures of the fifth lumbar often refer pain down the legs by irritation or pressure on the lumbo sacral nerves.

Remember, in examining back injuries, that we see few spines that are entirely normal. These injuries usually occur during the years of our active working life, and by that time most of us have some deviation from the normal. Remember, also, that there is considerable normal variation in the width of the vertebral bodies.

DOCTOR SPIERS (closing)—Regarding compression frac-

tures due to muscular violence, I have seen one which was unquestionably due to such. Several husky mechanics were testing their lifting ability at a garage. The champion, to demonstrate that he could lift still more, endeavored to lift a weight of about eleven hundred pounds. While in the extreme effort he suddenly cried out in pain and practically "froze" in the position in which he was standing. He was taken immediately to a hospital where x-rays films disclosed a compression fracture of the body of a vertebra. There was no bony pathology present causing any particular weakness to the spine.

Fractures of the transverse processes, in my experience, do cause long periods of disability at times. I have frequently found them among the hardest of cases to give symptomatic relief. I attribute this to the fact that the nerve trunks lie directly anterior to these processes.

I appreciate the discussion this paper has brought forth.

CALIFORNIA ASSOCIATION OF PHYSIOTHERAPISTS

(Reported by Beret Stenvig, secretary San Francisco Branch)

The San Francisco branch of the California Association of Physiotherapists held its meeting on March 11 in the form of a general discussion by the members of the association, with a very interesting and stimulating exchange of ideas on physiotherapy practice.

The next meeting will be on Wednesday, April 8, at 8 p. m. at St. Luke's Hospital, Twenty-seventh and Valencia. Richard W. Harvey, M. D., will speak on the use of hydrotherapy in the treatment of neurasthenia. Following Dr. Harvey's talk, the technician at St. Luke's will give a demonstration in the physiotherapy department.

The Family Doctor as a Community Asset—One of the inducements that leads to the setting up in a small village of a doctor's office is the rendering of service for hire. He locates in a community and grows up with the country and the people. He has succeeded them in sickness and in sorrow, has battled their diseases, rescued them in their accidents, warned, cheered and exhorted them. *He has been one of them.* He has not only been their physician and surgeon, he has assumed and earned a place of responsibility in their lives, and his interests have become so entwined and thought-bound with theirs that he is in the position of friend and counselor, and he not only is a country doctor, but he remains a country doctor.—Austin Flint, Iowa Medical Journal.

A Convalescent and Rest Home for Nurses—A group of New York women have purchased ten acres of land and provided suitable buildings, personnel, and financing for a convalescent and rest home for nurses. What a beautiful and worthy thought! The earning life of a good nurse is short, and the future after her active usefulness is too problematical. Even at the wages they now charge and to which many unjustly object, these worthy servants of the health of others cannot, even by practicing thrift, provide against the day when they can no longer earn a living. The well-thought-out plan now taking shape in New York might well interest benefactors of mankind elsewhere.

"Syphilis," says the Public Health Service, "may be held responsible for 52 per cent of all the deaths resulting from heart trouble, or 88,417 fatalities. When this sum is added to the 15,811 deaths credited to syphilis by the census figures, the result is a total of 104,228 deaths caused by syphilis directly or indirectly, and this total is arrived at without taking into consideration deaths caused by some other diseases which are in many cases a result of syphilitic infection. Experiments recently made in Paris would seem to indicate that 76 per cent of syphilitics have heart trouble."

EDITORIALS

BUNNELL MEMORIAL

It is fitting that the medical profession of California at the coming meeting in Yosemite Valley should honor the memory of the doctor who, in 1851 as a member of the Mariposa Battalion, the first white men to enter the valley, had imagination enough to appreciate the scenic wonders of the gorge. While his companions would have named it Happy Valley or something equally inane, Doctor Bunnell suggested that they name the valley for the tribe of Indians which lived there and which the battalion was pursuing.

The name "Yosemite" is otherwise appropriate, for it signifies the bear, to this day one of the denizens of the valley, typifying also the State of California.

The committee appointed at the Los Angeles meeting has had a plaque cast in bronze, commemorating Doctor Bunnell and his naming of the valley which, with permission of Mr. Stephen T. Mather, Director of National Parks, it is proposed to mount on a suitable rock at the foot of El Capitan, across the river from where the Mariposa Battalion made its principal camp in the valley, and dedicate it with appropriate ceremonies on Tuesday morning, May 19.

IS THE MEDICAL BAND GETTING TOO FAR AHEAD OF THE HEALTH PARADE?

Whenever the leading band gets too far ahead of the parade, the marchers not only get out of step and become confused, but groups of them are led off to side streets by the tunes of lesser attractions.

That a condition analogous to this is before us in the parade of medical and health progress, is attested by many facts which will readily occur to any reader. Surely, there is a band on every corner, each playing a different tune in a different key. Part of the leading band goes marching on, while other parts have turned back to see what has become of the parade. The paraders are confused and divided, as well they might be. Some are following this or that side show, while others drop into way-side inns for rest and sustenance. Corned beef and cabbage appeal more strongly to many than the blare of the canned music they are urged to follow. While aides of so many colors that they camouflage the whole situation rush up and down the lines exhorting, pleading, and commanding in a hundred tongues, nature, propelled by her inimitable and inexorable laws, rolls upon the paraders, taking toll from many who should be exempt if they only knew where to go and how to get there.

Every limb and branch of the tree of life has its group yelling at the tops of their voices that their branch is the main trunk of the tree, while others soar noisily through the air about until their gas is exhausted when they fall crushed, often taking with them some of the overloaded limbs of the health

tree. Is it any wonder that constantly increasing thousands of people are led to mistake the noise, the show, the shadows, for the substance of health? Having been uprooted from their generations of faith in a health leadership that marched close to and hand in hand with them by the razzle and dazzle of a thousand gaily colored lights flickered by false prophets, too many are growing weary of changing step and following where neither they nor their alleged leaders know.

One large group, for example, that has millions of followers, sets up scales, measuring-rods, and other mechanical devices as health diagnostic images for the ails of children. It does not require any particular intelligence to employ the images nor to interpret their readings. According to them, you either have, or have not "malnutrition," "undernutrition," or "overnutrition"—whatever these terms may mean. And having arrived at a diagnosis, you either take milk and vitamins or you don't. Like all "sure cures," based upon "sure fire," quick-acting, infallible diagnostic and treatment features, they do no measurable harm so long as there is nothing the matter. Just recently, there have been reported instances of chronic appendicitis, ulcers of stomach and intestine, tuberculosis, osteomyelitis, rickets, malaria, diabetes, and syphilis that had been diagnosed by totally incompetent persons as "malnutrition" by the use of mechanical diagnostic devices *and treated by milk and vitamins*. The outcome in more than one of these instances was needlessly tragic. One of these days public opinion is likely to be focused on a serious tragedy, and some "near doctors" are likely to be defendants in a manslaughter suit.

Another large group is pounding away upon the slogan of periodic health examinations. Health examinations of themselves have only a statistical value. It's the carefully written record of competent examinations and diagnosis placed in the hands of the person and his physician and followed up by them that is of value. This is precisely what is not being done extensively, nor is there any indication that it is what is wanted by those who make the most noise.

And so we might go on through many, many of the "loud-speaking" practices. Scales and weights furnish incomplete evidence of limited value; medical examinations furnish evidence of great value, *provided* only that in both cases the evidence is written, completed, and checked where necessary, *and* placed in the hands of the patient *and* his physician *and* followed up.

Let us, by all means, encourage the weighing and measuring of school children and all others. Let us have more and more health examinations, but we should stop the idea that is now being absorbed by millions of people that the one furnishes sufficient diagnostic data, or that either are end-results that mean health progress. The average citizen may be more of a moron than some of those who pronounce him so, but he is intelligent enough to understand a broader, more constructive, and more useful health message than he is now getting.

ADVERTISING AND ETHICS

Polk Daniels, in the Howard (Kansas) Courant, says: "Doctors don't advertise. Ethics prohibit. And so the opportunity is open for quacks to unload fake nostrums and cures upon the uninformed public. No wonder a French woman asked: 'What is an ethic?'"

"We have been accustomed and resigned to hearing this specious stuff," says the Medical Standard editorially, "but we are going to make one more effort, just the same, and rise to remark once more that it is specious and silly. WHAT IN THE WORLD HAS THE DOCTOR TO ADVERTISE? He puts up a shingle or a plate outside his door, and probably carries a card in his town newspaper if he lives in any other than a large city, and this announces to the public that he is a properly qualified practitioner examined and licensed by the state to treat the sick. If he is a specialist in some particular branch of medicine, his sign or his card announces that he treats diseases of the eye, ear, nose and throat, or diseases of children, or what-not. WHAT ELSE, IN HEAVEN'S NAME, COULD HE TELL?"

"... The argument that the doctor's refusal to go any further in advertising himself 'opens the opportunity for quacks to unload fake nostrums and cures upon an uninformed public' is both gratuitous and foolish. In the first place, even if that were true, it would not be a valid argument. That the quack, by utilizing improper means of exploitation, is able to put himself across is no justification for the decent practitioner employing improper methods of publicity. In a certain sense the unscrupulous man always has an advantage over a gentleman; he can and does perpetrate things that the gentleman's code prohibits him from doing. But to argue that the gentleman should adopt the cad's methods is an argument as silly and vicious as it is old. That being done, there would then be absolutely no way of differentiating the gentleman from the cad.

"But, as a matter of fact, the statement upon which the argument is based hasn't a grain of truth in it. The informing of the public on matters of true and false medical claims and medical achievement is not a subject for individual advertising, but for education and instruction at the hands of the profession at large; and everyone with a handful of sense knows perfectly well that in no department of human activity has there been such a widespread and efficient campaign of public enlightenment as in that which pertains to health and sickness and the treatment of the sick.

"So far from compromising with the methods of the quack, the decent methods of the profession have driven the old, rotten quack advertising from the face of the earth, and forced the quack to observe some form of decency, at all events. *The quack is on the defensive nowadays. In order to survive at all, he has to pay the homage which vice pays to virtue, and imitates the reputable physician.*

"*An uninformed public—tra-la-la! The public, in the main, knows quite well the difference between the reputable medical man and the quack. The trouble is that a large proportion of the dear public actually like quackery; and that will be true for a long time to come. And if, as our critics suggest, the reputable medical practitioner were to throw ethics to the winds and advertise in the same manner as the quack, that portion of the public would turn to him, not because he was a reputable, decent practitioner, but because they would take him to be a quack.*"

There is still another phase of Mr. Daniels' criticism of medical ethics. He overlooks the fact that his public press also has a code of ethics even longer than that of physicians. His code, among other things, stands for "*truth in advertising.*" Admitting as he does that quacks advertise, we would like to ask him what he does with *his* ethics when he accepts a quack's advertising copy. Most good newspapers live up to their ethics as do most good doctors, but still far too many of both classes skate

along the edge of honesty and some still continue to slop over.

It is pretty poor taste for a paper or periodical to criticize doctors for trying to live up to a moral code of procedure because that code prevents the periodical from selling space for unworthy purposes, while at the same time the publication sells space for purposes which the ethics of its own profession prohibits.

"Truth in advertising" in essence is part of medical ethics as it is of newspaper and magazine advertising ethics.

We should all "hold fast to that which is good."

THE FUTURE OF THE MEDICAL PROFESSION

In his presidential address before a branch of the British Medical Association, Thomas MacCarthy speaks conservatively of a situation that is only a few jumps ahead of us and on the road we are traveling in high with the gears locked. Among the things he said were that: "It is well that we should consider from time to time non-scientific subjects which concern the honor and welfare of our profession. The pressure of hard circumstance has compelled us to spend much time and thought on medico-political matters during past years, more especially since 1912 (when the compulsory health insurance went into effect), and this has been necessary unless we were content to allow the best interests of our profession to go by default. By interests I do not mean merely, or even mainly, financial ones, but our professional interests in the art of healing. We have been engaged in a hard struggle to maintain what is best, and have had to contest the ground foot by foot. We are still doing so, and I can see no chance of any surcease from strife in the immediate future, but rather from time to time fresh exacerbations of it. . . ."

"It is commonly and truly said that change of occupation is as good as a holiday, but he would be a bold man who advised the overtaxed doctor to turn his thoughts, as a relaxation from his professional work, to the consideration of the medico-political problems with which he is surrounded and oppressed. Nevertheless, it is of the first importance to all of us, and to those who come after, that we should try to work our way through these difficulties. . . ."

"As a profession we are prone to go on doing our work, striving to keep up with the progress of science in so far as it concerns the practice of physic, and not to heed the changes in social and political thought and the effects these must have on our profession, until a momentous change rapidly comes within the range of practical politics and soon is an accomplished fact, leaving us stampeded by its apparent suddenness. Such a change is often called revolutionary. At first sight it may seem so, but most of the changes are evolutionary and of comparatively slow growth. The actual change is sudden, but the factors producing it are of a steadily accumulating nature. One with eyes to see can tell what the gradually increasing weight must do some time before the catastrophe occurs.

"The days are gone, never to return, when the

doctor can plough his furrow in his own way, thinking only of his patient and how best to treat his malady, working just as an individual and according to his conscience. For good or ill the state has stepped in, or, perhaps more properly, has put both feet in, and in the future will interfere more and more with what it considers to be the interests of its citizens. The health of the community is of such importance that the state feels that the best skill and attention must be available for everyone, and apparently is on the way to making medical service a national one, as the army and navy are.

"Things have progressed too far to go back on these arrangements; we must accept them as they are, . . . for the only alternative to the present system is a whole-time state medical service, which, in the best interests of the community, we wisely side-tracked by accepting the panel system. . . .

"There are about 13 millions of insured persons in England and Wales, and the ministry of health estimates their dependents at 17½ millions. The inclusion of these latter for medical attendance has been in the minds of many from the very beginning, but it was thought better to start on the workers as being a more manageable and less expensive matter, and if this proved a success the addition of the dependents would follow. It is fairly obvious that adequate treatment is just as necessary for the dependents as for the insured person in the interests of public health. Financial stringency is a bar, but we must remember that where the health of the community is at stake, or (what amounts to the same thing) is thought to be at stake, money will be found. When and if this extension takes place there will be over 30 millions of the population attended on the panel system. Secondly, there is an insistent and growing demand for an extension in the range of medical services for insured persons, to include everything—operation, consultations, specialist services. This is being pushed forward very vigorously at the present moment, especially by the approved societies, and cannot be long delayed.

"It does not require much imagination to realize that the increase in number from 13 to 30 millions, coupled with the scheme embracing all kinds of medical services, must greatly alter medical practice for us all, and make us to a still greater extent a state-paid and state-regulated profession. At present only general practitioners are intimately concerned, and not all of these, but with the extensions foreshadowed still larger proportion of these, and even specialists and consultants, will be involved. Another important factor is the hospital question. This is a large and complex matter which is causing a great deal of discussion with, so far, apparently little result. It is, however, slowly crystallizing, and a few years will find us at grips with it as we now are with the panel question.

"A satisfactory solution of this hospital question is a matter of great importance to all who do hospital work, but I do not propose to enter into it save to suggest that the voluntary system, which is so in keeping with the genius of this country and under which such a high state of efficiency has been

attained in hospital service, is not likely to continue much longer."

ALCOHOL AS A METABOLITE IN NORMAL TISSUES

Ever since W. Hutson Ford of New Orleans demonstrated (in 1872) that tissues of animals contain preformed alcohol, investigators have debated from time to time the possible origin of this normal alcohol. The quantity and concentration, of course, are not very large, though large enough to permit quantitative estimation. Pringsheim and Schweisheimer estimated the following concentrations: Rabbit blood, 0.0018 per cent; rat muscle, 0.0028 per cent; rat liver, 0.0023 per cent; human blood, 0.0029 to 0.00367 per cent. Although these concentrations appear trifling, they are not so small when they are compared with certain ordinary metabolites of the blood, and with reported concentrations of alcohol after its oral administration. For instance, Miles found the concentration in blood during the first two hours after taking one liter of 2.75 per cent alcohol to be from 0.018 to 0.03 per cent, and 0.028 to 0.036 per cent after taking 100 cc. of 27.5 per cent alcohol. The appearance of alcohol in blood and organs of individuals not receiving it suggests its origin from the dietary or tissues, or both. Its origin appears to be rather complicated. The fact that the blood alcohol varies somewhat with carbohydrate diet indicates that the class of carbohydrates is responsible in part, at least.

Recently, Kühn of Jena has suggested the following schematic representation of its formation from sugar; dextrose → glycerine and triose → d-lactic acid → d-alanin and pyrocatechuic acid → acetoacetic acid, acetaldehyde and ethyl alcohol → acetic acid, which is finally oxidized to carbon dioxide and water. Accordingly, ethyl alcohol may be regarded as an intermediary product of carbohydrate metabolism, a fact perhaps hitherto insufficiently appreciated. As long as the alcohol does not exceed certain concentrations, it would hardly be regarded pharmacologically as a protoplasmic poison. However, the information regarding the concentrations in disease conditions, in anomalies of metabolism, and the effects from low concentrations over very long periods is lacking. The few existing investigations of the concentration of alcohol in blood and cerebrospinal fluid of normal and alcoholic individuals after ingestion of alcohol under practically acute conditions do not furnish the information desired about disease and chronic conditions. The recent studies of Kühn do not quite meet these latter requirements, but are nevertheless worthy of attention.

Kühn studied the blood alcohol of abstinent students from 21 to 26 years old, during starvation, on a carbohydrate diet and after the administration of small quantities of alcohol. The concentration in the blood of starved subjects ranged from 0.0006 to 0.0051 per cent, average 0.00154 per cent, which is about one-third of that claimed previously. These figures were not changed when the subjects were on a liberal carbohydrate diet. After the administration of from 18 to 26.6 cc. of absolute alcohol with liberal carbohydrate diet, the alcohol content increased to an average of 0.0033 per cent, the maximum con-

tent found at the end of an hour being 0.0057 per cent. The blood alcohol, after drinking two bottles of German beer, with a liberal carbohydrate diet, was less than the blood alcohol on the diet alone. The cause of this inhibitory influence of the dietary was not ascertained, but some interference with the absorption of the alcohol of the ingested liquor is suggested. A curious feature is that the blood alcohol of carbohydrate dietary alone was decreased when alcohol was taken with the diet, as though the presence of alcohol in the alimentary tract prevented or inhibited the process originating dietary alcohol. From this it is suggested that the blood alcohol of dietary has a fermentative origin in the alimentary tract which leads up to a further suggestion, namely, that blood alcohol might serve as a useful criterion of intestinal fermentation and putrefaction, instead of the blood phenol frequently employed.

The fermentation theory of blood alcohol is not new, but neither the theory nor the entire question of blood alcohol have received the attention that they appear to merit. The work of Kühn does not quite agree with the results of the older investigators, but it has the merit of having been done with accuracy and of calling attention again to a matter that deserves more than passing notice.

UNIVERSITY OF CALIFORNIA MEDICAL SCHOOL OPENS GRADUATE SUMMER COURSES

Announcements have been sent out that the University of California Medical School and the University of California Hospital will give summer courses to graduates in medicine, surgery, and medical specialties between dates of June 15 and July 11. Doctor Eugene Kilgore is director of the courses.

PRACTICAL THERAPEUTICS AND THE ART OF MEDICINE

Abstracts from Alumni Lectures, University California Medical School, 1924

Dr. Dewey R. Powell—I would rather do \$100 worth of work for \$25 and know the person will be able to pay without depriving his family of the necessities of life, thereby gaining a friend, then charge \$75 or \$100 and have it pain in small dribbling amounts and leaving the impression of being overcharged.

Dr. James Sewell—You will be called on to take an active part in politics in the community in which you reside. You should regard it as your duty. If we are to have a free country, if we are to have a country we can love and respect, we must all take part in its government. You don't need to be too active nor too partisan, but pay enough attention to what is going on, so if patients ask for advice—as they do—you can tell them what to do.

Dr. J. Wilson Shiels—The "old doctor" should not pass. As a matter of fact, the young, well-educated medical man can, in reverence, emulate him.

EDWARD N. EWER, M. D., Oakland.....President-elect
EMMA W. POPE, M. D., San Francisco.....
.....Secretary and Associate Editor for California

YOSEMITE AND THE ANNUAL SESSION, MAY 18-21, 1925

Spring comes early to Yosemite National Park. Already the meadows are turning green and soon they will be filled with all kinds of blossoms which have given Yosemite the sobriquet of "The Park of a Thousand Flowers." There will be Mariposa lilies, snowplants, evening primroses, and scores of less famous flowers, blooming in the emerald meadows or in the rich forest mold underneath the giant trees.

However, this article is not to be an adjective-laden description of Yosemite's natural charms, of which everybody knows, but a precise statement of what kind of weather may be expected by the members of the California Medical Association during the annual convention May 18 to 21. Of course, it is impossible to predict, but official government records of weather conditions over a long period of years certainly will be indicative of possibilities.

"One often reads praises and generalities about Yosemite climate and weather," says Park Naturalist Ansel F. Hall, in his most excellent book, "Handbook of Yosemite National Park," "but, so far as the writer knows, no concise statement as to exactly what might be expected at any given time of year has ever been published.

Recent reports from the Valley Incomparable indicate an early spring, and May should be unusually beautiful. Heavy snows during the winter will make the falls run in large volume and the plant life extremely luxuriant. The Wawona Road will probably be passable in April this year, so that those professional men who desire to drive to Yosemite in their own automobiles should find the road in good condition the middle of May. The majority of the visitors doubtless will go the easier and more beautiful route by train via Merced to El Portal through the canyon of the Merced River and the old gold diggings, and by Yosemite Transportation System automobiles, fifteen miles over the government boulevard from El Portal to Yosemite Valley, still paralleling the Merced River and passing through the famous "Gates of Yosemite," where El Capitan stands on one side, Three Graces and Bridal Veil Falls on the other, with a wonderful vista in the distance.

The road from Yosemite Valley to the Mariposa Grove of Big Trees also will be open during the convention, affording delegates and their families the opportunity to see what experts say is the finest of all groups of sequoia gigantea. The Yosemite Transportation System will operate daily motor-car trips during the convention from Yosemite Valley to the Mariposa Grove of Big Trees by way of Artist and Inspiration Points. Another interesting trip operated daily is the tour of Yosemite Valley.

ANNUAL SESSION C. M. A., YOSEMITE, MAY 18, 19, 20, 21, 1925

The Fifty-fourth Annual Meeting of the California Medical Association promises to be well attended, 400 reservations having already been made.

Due to the most efficient co-operation of section secretaries, the completed program appears in this issue of CALIFORNIA AND WESTERN MEDICINE. The program holds much of interest for the membership, and should secure a good attendance at section meetings, despite the counter-attractions of beauty and grandeur in our wonderful Yosemite Valley.

The March issue should be referred to for any information concerning hotel rates and train schedules.

DELEGATES AND ALTERNATES TO A. M. A.

California delegates to the A. M. A., with their corresponding alternates, are:

Victor G. Vecki, San Francisco, 1925; alternate, C. Van Zwalenburg, Riverside, 1925.

Hans Lisser, San Francisco, 1925; alternate, William E. Stevens, San Francisco, 1925.

Albert Soiland, Los Angeles, 1925 and 1926; alternate, Charles D. Lockwood, Pasadena, 1925 and 1926.

Robert V. Day, Los Angeles, 1925 and 1926; alternate, Robert Pollock, San Diego, 1925 and 1926.

Lemuel P. Adams, Oakland, 1925 and 1926; alternate, O. D. Hamlin, Oakland, 1925 and 1926.

For full details, see minutes of 150th meeting of the Council, as published on this page.

ABSTRACTS FROM THE MINUTES OF THE ONE HUNDRED AND FIFTIETH MEETING OF THE COUNCIL OF THE CALIFORNIA MEDICAL ASSOCIATION.

Held in the offices of the editor of CALIFORNIA AND WESTERN MEDICINE, 806 Balboa Building, San Francisco, California, Saturday, February 14, 1925, at 10 a. m.

Present—Doctors Parkinson, MacGowan, Ewer, Alderson, Musgrave, Kinney, Kiger, Edwards, De Lappe, McArthur, Gibbons, Hamlin, and Pope.

Absent—Doctors Beattie, Coffey, Smith, McLeod, Bine, Kress, Curtiss, and General Counsel Peart.

The secretary reported that Rene Bine and General Counsel Peart were both unable to attend because of illness. G. H. Kress of Los Angeles and C. L. Curtiss of Redlands were also unable to attend because of illness. Letter from J. H. McLeod of Santa Rosa was then read, in which he conveyed his regrets that he would be unable to attend any but the evening session.

Minutes of the Council—On motion of Kiger, seconded by McArthur, it was

RESOLVED, That the minutes of the 148th and 149th meetings of the Council as mailed to each member thereof be approved.

Minutes of the Executive Committee—The secretary read the minutes of the 79th and 80th meetings of the Executive Committee.

Action by the Council—On motion of Kiger, seconded by Gibbons, it was

RESOLVED, That the minutes of the 79th and 80th meetings of the Executive Committee be approved and made an official part of the minutes of this Council.

Resignation of T. C. Edwards as Delegate to A. M. A.—T. C. Edwards of Salinas presented his resignation as a delegate to the A. M. A.

Action by the Council—On motion duly made, the resignation of T. C. Edwards of Salinas as a delegate to the A. M. A. was accepted.

Delegates to A. M. A.—The secretary reported that, by reason of the increase in membership, the C. M. A.

was now entitled to five delegates and five alternates to the A. M. A., and also stated that it would be impossible for the California House of Delegates to elect the necessary delegates and alternates at its annual meeting on May 20 and comply with the requirements of the A. M. A. That it would, therefore, be necessary for the Council to take some action in the matter prior to the annual meeting, in order to secure the proper certification of delegates at the A. M. A. convention; such action to be later confirmed by the California House of Delegates. The following are those delegates with corresponding alternates, whose terms expire: Albert Soiland, Los Angeles; alternate, Robert V. Day, Los Angeles. John C. Yates, San Diego; alternate, Charles D. Lockwood, Pasadena.

Action by the Council—On motion of McArthur, seconded by Kiger, it was

RESOLVED, That Albert Soiland and Robert V. Day, both of Los Angeles, be elected as delegates to the A. M. A. for the ensuing two years.

Alternates to A. M. A.—On motion of Kiger, seconded by McArthur, it was

RESOLVED, That Charles D. Lockwood of Pasadena be elected as alternate to Albert Soiland of Los Angeles for the ensuing two years; and that Robert Pollock of San Diego be elected as alternate to Robert V. Day of Los Angeles for the ensuing two years.

Delegate to Replace T. C. Edwards, Resigned—On motion of Alderson, seconded by Gibbons, it was

RESOLVED, That Hans Lisser of San Francisco be elected delegate to the A. M. A. to fill the unexpired term of T. C. Edwards of Salinas, resigned; William E. Stevens of San Francisco remaining as alternate to Doctor Lisser.

Fifth Delegate to A. M. A. Under 1924 Apportionment—The election of a fifth delegate and corresponding alternate as apportioned by the A. M. A. for the 1925 session and thereafter was brought up. The question was then raised as to whether such representatives should be elected from the North or the South, to conform with the usual custom of giving equal representation to the North and the South.

The Chair suggested that it be decided by lot from what district the fifth delegate should be elected for the 1925 and 1926 sessions. The decision fell to the North; and it was the sense of the Council that, at the expiration of such term the fifth delegate would be elected from the South and, thereafter, alternate each second year between the North and the South. The election of the fifth delegate and alternate was postponed till the afternoon session.

Election of Trustee of Indemnity Defense Fund—The secretary advised the Council that the term of William Duffield of Los Angeles as a trustee of the Indemnity Defense Fund had expired January 1, 1925.

Action by the Council—On motion of MacGowan, seconded by Alderson, it was

RESOLVED, That William Duffield of Los Angeles be elected to succeed himself for the ensuing three years as a trustee of the Indemnity Defense Fund.

Medical Radio Broadcasting—The secretary read a report from the Committee on Medical Radio Broadcasting as submitted by the chairman, George H. Kress of Los Angeles. This report and the question in general was then fully discussed.

Action by the Council—On motion of Ewer, seconded by Gibbons, it was

RESOLVED, That the report of the Committee on Medical Radio Broadcasting be adopted as submitted, and that action be taken as outlined therein.

Membership Directory—The Chair raised the question of including in the membership directory the home address, as well as the office address, and both telephone numbers of all members; and recommended that such additions be made to the next directory.

Action by the Council—On motion of McArthur, seconded by De Lappe, it was

RESOLVED, That the home address, office address, and both telephone numbers of all members be included in the next issue of the membership directory.

Income Tax Deductions—The president submitted the following amendment to the Revenue Act as prepared by the general counsel, in accordance with instructions re-

ceived at the last Council meeting. (Words in italic type comprise the proposed amendment.)

"Sec. 214 (a). In computing net income, there shall be allowed as deductions: (1) All the ordinary and necessary expenses paid or incurred during the taxable year in carrying on any trade, business, *or profession*, including a reasonable allowance for salaries or other compensation for personal services actually rendered; traveling expenses (including the entire amount expended for meals and lodging) while away from home in the pursuit of a trade or business, *or profession, or in attending professional conventions of the profession of which the taxpayer is a member.*"

The president then stated that the best way would be to have some member of the House of Representatives present this amendment and have the united medical profession of the country support it.

Action by the Council—On motion of De Lappe, seconded by McArthur, it was

RESOLVED, That the amendment to the Revenue Act as proposed by the general counsel be adopted; and that the secretary be instructed to take the necessary steps to have the amendment passed, and to place the matter before the various state medical, bar, and other professional associations of the Union.

Legislative Procedures—The secretary read, for the information of the Council, a report submitted by the general counsel regarding legislative procedures. No action was taken.

Application for Affiliate Membership—The secretary presented an application from Doctor J. S. Wheeler of Lincoln for affiliate membership, together with endorsement of such application by the secretary of the Placer County Medical Society.

Action by the Council—On motion of Alderson, seconded by Ewer, Doctor J. S. Wheeler of Lincoln was elected an affiliate member of the California Medical Association.

Status of Associate Members of County Medical Societies—The secretary read a letter from Councilor Kinney, covering the situation now existing in San Diego County and calling attention to discrepancies in the state constitution and by-laws regarding associate membership. The secretary then reported that the general counsel suggested that the Council temporarily take care of the situation and that he would prepare an amendment to the constitution for presentation at the annual meeting.

After full discussion, it was the sense of the Council that no action be taken in the absence of a report from the general counsel, and that the matter be postponed till the annual meeting.

History of the California Medical Association—Suggestion of Councilor Kress of Los Angeles that the Council appoint a "Committee on the Preservation of the History of the California Medical Association" was considered. The Council was informed that there were several medical historical societies now in existence in California.

Action by the Council—On motion of McArthur, seconded by Kiger, it was

RESOLVED, That the chairman, if deemed wise after a thorough investigation, be authorized to appoint a committee of three or five on the "Preservation of the History of the California Medical Association"; and further that the chairman be included in the membership of such committee.

Financial Statements—Detailed statements of the finances of the California Medical Association and California and Western Medicine were presented for discussion, in accordance with instructions given at the last Council meeting; copies of such statements having been mailed to all members of the Council.

After general discussion, it was the sense of the Council that financial statements be included in the report of the Council to the House of Delegates and, at the same time, that the association be advised that every fraternal publication must be credited with one-half the subscription price of such publication for every member of the association.

Present Status of the Journal—The editor reported that in 1924 the Journal had published 1536 pages, 864,000 words of reading matter, exclusive of advertising; 117 original articles, and had rejected 19 manuscripts. He also advised that on February 14, 1925, 127 accepted but unpublished manuscripts were on hand, which did not include the material for the Historical (May) number; and that this is more than a year's supply of articles. He then requested recommendations or suggestions as to how this congestion was to be relieved; whether by adding another folio and thereby increasing materially the cost of the Journal, or by being more critical in accepting manuscripts. After a full and general discussion, the editor submitted the following resolution:

"WHEREAS, The increasing prominence of CALIFORNIA AND WESTERN MEDICINE is resulting in a marked increase in the number of articles offered for publication, thus amplifying the editor's responsibilities in deciding what to accept and what to decline, now, therefore, be it

"RESOLVED, That the editor is authorized and instructed to arrange with such members of the California Medical Association as he sees fit to serve as members of an editorial council. It shall be the duty of these editorial councilors to advise with and assist the editor with his problem of accepting and declining matter submitted for publication. Following the usual custom of periodicals, the names of members serving on this council will be kept confidential between the editor and each member."

Action by the Council—On motion of Edwards, seconded by McArthur, it was

RESOLVED, That the resolution as submitted by the editor be adopted as the sense of the Council; and that the question of relieving the congestion in the publication material for CALIFORNIA AND WESTERN MEDICINE be further considered and made a part of the report of this Council to the House of Delegates, together with the financial report for 1924 and the outlook for 1925.

Subscription Price of Journal—The editor recommended that the paid subscription price of CALIFORNIA AND WESTERN MEDICINE be increased to \$5 per year and 50 cents per single copy, as the actual cost of publishing the Journal is more than the present subscription price, which is \$4 per year.

Action by the Council—On motion of MacGowan, seconded by Gibbons, it was

RESOLVED, That, commencing with the March issue of CALIFORNIA AND WESTERN MEDICINE, the paid subscription price be fixed at \$5 per year and 50 cents per single copy.

Publication Cost of Journal—The secretary presented a report from the James H. Barry Company covering the present publication cost of CALIFORNIA AND WESTERN MEDICINE, as requested by the Executive Committee at its last meeting.

Action by the Council—On motion of Edwards, seconded by McArthur, it was

RESOLVED, That the Council, having heard the report of the James H. Barry Company on the present publication cost of CALIFORNIA AND WESTERN MEDICINE, recommends that commencing with the March issue, the cost to the Journal be based on the following monthly rates: Five thousand copies, 128 pages and cover, \$1,600; additional 100 copies, \$26.25; this being an increase of approximately 5 per cent over the present cost.

Commissions on Journal Subscriptions—The question of paying commissions on Journal subscriptions, as referred to the Council by the Executive Committee, was considered.

Action by the Council—On motion of Kiger, seconded by De Lappe, it was

RESOLVED, That, upon recommendation of the editor, the payment of commissions on subscriptions to CALIFORNIA AND WESTERN MEDICINE be not approved.

Legislative Matters—Mr. Celestine J. Sullivan, executive secretary of the League for the Conservation of Pub-

lic Health, being present by request, submitted a digest of the medico-legal bills now before the Legislature, which were then fully discussed.

Action by the Council—On motion of McArthur, seconded by Kiger, it was

RESOLVED, That the Council, having heard the report of the League for the Conservation of Public Health on proposed legislation touching public health and public welfare, believes that such measures should have wide publicity to elicit comment and suggestions from those interested.

Election of Fifth Delegate to A. M. A.—On motion of Kiger, seconded by Alderson, it was

RESOLVED, That Lemuel P. Adams of Oakland be elected as the fifth delegate from the California Medical Association to the American Medical Association for the ensuing two years.

Election of Fifth Alternate to A. M. A.—On motion of Kiger, seconded by Alderson, it was

RESOLVED, That O. D. Hamlin of Oakland be elected as alternate to Doctor Lemuel P. Adams for the ensuing two years.

Clinical Prize—The Chair reported that he desired to confer with Councilors Bine and Kress, both of whom were absent, before appointing the "Committee on Clinical Prizes," and, therefore, requested further time, stating that the matter would be included in the annual report of the Council, and in that manner would go before the association as a whole.

It was the sense of the Council that the matter be referred over to the next meeting.

Medical Section of Officers' Reserve Corps—The Chair reported that he had succeeded in securing from the Surgeon-General's office a list of the Reserve Officers in California, and that it was the Surgeon-General's desire that members of this committee be composed of members of the Reserve Corps and those who would be most influential in securing members for the corps.

After discussion, it was the sense of the Council that a statewide committee of fifteen be appointed to function separately from the California Medical Association, but that the personnel of such committee be limited to members of the association only; and that further time be extended the Chair in the matter of appointment of such committee.

Attendance at Council Meetings—The question of attendance at Council meetings was considered, and the secretary was instructed to ascertain if there was any ruling or section in the old records or constitutions prior to 1900 that covered this point.

Sciences Allied to Medicine—The secretary reported that, in accordance with instructions received at the last Council meeting, she had endeavored to secure a ruling from the A. M. A. as to "what constitutes sciences allied to medicine"; and that the secretary of the A. M. A. had just wired that the Judicial Council was still considering the question and that it would probably be some time before a decision was reached. Pending receipt of a report from the A. M. A., no action was taken.

Status of Legal Department—The secretary presented, for the information of the Council, a brief report prepared by the general counsel on the present status of the legal department.

Expression of Regret—The secretary was instructed to convey to the General Counsel and those members, whose illness prevented attendance, the sincere regrets of the Council at their enforced absence from this meeting.

Report of Committee on Prenatal Care—The secretary presented the report of the Committee on Prenatal Care as submitted by the chairman, Reginald Knight Smith.

It was the sense of the Council that the secretary be instructed to furnish mimeographed copies of this report to each member of the Council, as the length and importance of this report demanded more detailed considera-

tion; and that each Councilor be requested to return his signed copy with suggested changes or approval.

Adjournment—There being no further business, the Council adjourned to hold an open meeting with the Committee on Industrial Medical Practice.

ALAMEDA COUNTY

Alameda County Medical Society (reported by Pauline S. Nusbaumer, secretary)—At the regular meeting of the Alameda County Medical Association held February 16, the following program, arranged by George Rothganger, was presented by the staff of Merritt Hospital:

A case report of diabetes complicated by gout was given by Hobart Rogers and A. H. Rowe, and was followed by a symposium on the treatment of fractures of the extremities. "The Closed Treatment," by Sumner Everingham; discussion opened by H. H. Hitchcock. "Treatment by Open Operation," by Mark L. Emerson; discussion opened by F. J. Carlson. "Treatment of Complications," by Warren B. Allen; discussion opened by D. N. Richards. "Treatment of Non-union," by George Rothganger; discussion opened by W. L. Bell. In his paper, "Closed Treatment of Fractures," Sumner Everingham said that careful early treatment of fractures is essential to give best results anatomically and functionally; that of prime importance is an x-ray to (1) demonstrate the presence of a fracture, (2) the variety and position of the fragments, (3) a co-existing dislocation, and (4) the presence of gas gangrene; that the essentials for successful treatment of long bones are (1) to replace the broken ends at the earliest possible moment, (2) proper retention until nature has provided for adequate healing in restoring the continuity, (3) adequate supervision of the nutrition and function of the soft parts by massage, electricity, passive and active motion. In discussing "The Open Treatment of Fracture," M. L. Emerson said that less than 2 per cent of fractures are subject to open treatment. Wire of some type is still pre-eminent as a means of fixation. In regard to the discussion of which is the better in non-union—internal medullary beef bone splint, external periosteum osteal sliding graft, or wire. He suggests the use of all three. Perhaps one of them will give the desired results. He advises against putting one's faith in any *one* method. The doctor has discarded the use of kangaroo tendons in any type of bone work. In the treatment of fracture complications, Warren B. Allen calls special attention to injured parts following fracture to prevent thrombosis and embolism. He thinks that symptoms of fat embolism are frequently overlooked. The writer claims that the diagnosis of fat embolism is facilitated by finding fat globules in the urine. The doctor also states that nerve injuries frequently are not discovered until the splints have been removed weeks later, and he gives hemorrhage into joints as a cause for ischemic paralysis. In his paper George Rothganger stated non-union should be distinguished from delayed union, which follows so frequently upon crushing and automobile fractures. Failure of union in the great majority of cases is due to malposition, occurring rarely with good contact of fragments. In such cases of malposition excision of the overlapping ends and correction of the displacement is satisfactory. In those with loss of substance and in the rare cases of non-union with good approximation, some type of transplant must be used, the writer giving the special type for each long bone.

As is the custom after the close of the program, refreshments and a social hour were enjoyed.

The annual banquet of the association was celebrated on Wednesday evening, February 18. Some 150 of the members attended. Spring flowers in profusion formed the decorations upon all of the twenty odd tables.

The speakers' long table at the head of the room was occupied by the speakers and the officers of the association and O. D. Hamlin and S. H. Buteau, two of the deans of the medical profession of Alameda County. The president gave a brief address of welcome, and vocal music was dispensed throughout the evening.

One of the interesting pleasantries was an address by E. N. Ewer on many original topics of the day regarding the profession and the public, which was not only interesting and pleasing, but subtle in the extreme. The speaker of the evening was Mr. Franklin H. Kean. His

subject was "The Physician as the Man." Mr. Kean held his audience enchanted from the opening to the closing of his address.

Judged by the expressions of enjoyment by the guests, the evening was very worth while, and the president, H. B. Mehrmann, has every reason to be proud.

At the regular meeting of the Merritt Hospital Council held February 2, Charles L. McVey president, the program was divided into three main sections: 1. Hospital betterment under which any member is invited to offer suggestions or participate in discussions. 2. The paper of the evening, "Liver Abscess," by W. E. Mitchell. 3. Case and autopsy reports, mistakes in diagnosis, new therapy or technique, etc., any number invited to take part.

✱

CONTRA COSTA COUNTY

Contra Costa County Medical Society (reported by L. St. John Hely, secretary)—The regular monthly meeting of the Contra Costa County Medical Society was held at the Women's Clubrooms at Walnut Creek, Saturday, February 28, under the direction of J. Emmett Clark. The meeting was called to order at 9:30 p. m. by the president, Dr. Denninger-Keser. The minutes of the previous meeting were read and approved.

Discussions were entered into and a motion made and carried that each program chairman would have three months' notice to prepare for the meeting, to get speakers, place of meeting, etc. This was adopted as a permanent ruling. A committee of three was appointed, two members to hold office for the year, and for the third, the special program chairman appointed for the one meeting. J. Emmett Clark was appointed as the permanent member for the year 1925. The secretary will always be the other, as he will be in a position to handle all the correspondence.

The next meeting will be held at Martinez.

The speaker of the evening was George Warren Pierce of San Francisco. His subject was "Care of the Injured Hand." He illustrated his lecture with lantern slides, and handled the subject in a masterly style. We were very fortunate in securing him, as he is master of the subject. The following members were present: George McKenzie, J. Emmett Clark, E. C. Love, E. Merrithew, John Beard, Rosa A. Powell, H. L. Carpenter, Denninger-Keser, L. St. John Hely, C. R. Leech.

✱

FRESNO COUNTY

Fresno County Medical Society (reported by T. Floyd Bell, secretary)—A meeting of the board of governors of the Fresno County Medical Society was held March 2, 1925, in Dr. Anderson's office. Drs. Couey, Cross, Miller, Tillman, Anderson, and Bell present.

Bills were audited and ordered paid. The secretary announced the withdrawal of the application for membership of Dr. H. Robertson. (Note: Through a publication error, Dr. Robertson was reported last month elected to membership.)

The president and secretary were instructed to act as delegates to the general council of the Fresno Community Chest.

In regard to the examination of children entering school for the first time, Miller moved, Tillman seconded, that the board recommend that the society undertake such examinations as requested by the Children's Bureau of the State Board of Health and the Fresno City School Department. Uniform examination blanks were requested. These examinations are to be done in the offices of the family doctors free of charge. Carried.

Drs. Anderson and Cowan were requested to again interview officials of the San Joaquin Light and Power Corporation, to see if they are going to take action as promised to discontinue medical aid to families of employees free of charge, and if so when.

A communication from Dr. J. C. Drake of Kerman was read in regard to nurses of the Sun-Maid Raisin Growers practicing medicine and surgery. The president was authorized to appoint a committee, he being chairman, to take this matter up with Mr. Ralph Merritt. Drs. Anderson, C. D. Collins, T. F. Madden, J. D. Morgan, were appointed.

The secretary was instructed to get more data from the

Red Cross nurse about the prescribing of medicines by an alleged doctor at one of the local drug stores.

Several matters of proposed state legislation were discussed.

The regular meeting of the Fresno County Medical Society was held March 3, at the Nurses' Home of the General Hospital. There were thirty-five members and eleven visitors present. Members—Allen, Aller, Anderson, Bell, C. D. Collins, Couey, Craycroft, H. O. Collins, Diedrich, Dahlgren, Dau, Goldberg, Hopkins, Kjaerbye, Lamkin, Larson, Manson, Mathewson, Miller, Mitchell, Hilholland, Madden, Newton, Nider, Pettis, Schottstaedt, Sheldon, Staniford, Stein, Tillman, Vanderburgh, J. R. Walker, Weddle, Wheeler, and Willson. Visitors—Shiels, McClure, Newbecker, Yocum, Tourtillott, and interns from the General Hospital.

The communication was read from Dr. J. C. Drake, and the action of the board of governors in regard to same was approved.

In regard to examination of children entering school for the first time, Madden moved, Tillman seconded, that the recommendation of the board of governors be adopted. Carried.

Dr. Madden, as chairman of the staff of the General Hospital, gave a cordial invitation to members of the profession to attend the monthly staff meetings the second Tuesday of each month.

Staniford moved, Madden seconded, that a committee of three be appointed to investigate the merits of the San Joaquin Valley Health Association, particularly the work of the Nutritional Home. Carried. Cowan, H. O. Collins, and Dau appointed.

J. Wilson Shiels of San Francisco was the speaker of the evening. He presented three interesting cases from his clinic, presenting diagnostic difficulty.

The first patient was one of fifth nerve palsy who first complained greatly of pain in the eyes. Physical examination showed all three branches involved without any other pathology anywhere in the body, except a slight irritation in the spinal fluid and blood gave strong Wassermann reactions. Under treatment he cleared up well. However, the prognosis was poor on account of the parietic gold chloride curve in the spinal fluid. He showed charts of the fifth nerve anatomy to refresh the minds of the audience on same.

The second case was one of aneurism of the anterior cerebral artery with eventual rupture and death. He said that aneurism of cranial vessels was very seldom luetic, but usually due to some other pathology in the walls of such vessels, such as arteriosclerosis, infection, etc. The symptoms in this case were very acute. He pointed out that acute brain conditions are mostly due to tumors of some kind. He showed the pathological specimen removed at necropsy.

The last case showed a very interesting and rare condition of gumma of the mediastinum. This was illustrated by radiographs of the chest during various periods of treatment, and showed the marked improvement by the use of mixed treatment by mouth and mercury rubs, without salvarsan.

A buffet luncheon was served after the meeting.

✱

ORANGE COUNTY

Orange County Medical Society (reported by D. R. Ball, secretary)—The thirty-seventh annual banquet of the Orange County Medical Association was held at the new Ebell Clubhouse in Santa Ana the evening of January 6. The social program included vocal and instrumental selections, and music by the Santa Ana Symphony Orchestra. On the request of toastmaster, Dr. F. E. Coulter, responses were made by Rowland P. Yeagle, retiring president; Dr. H. D. Newkirk, incoming president; C. D. Ball, J. I. Clark, Mrs. J. P. Brastad, and the Reverend Walter Thornton. The officers for the new year were duly installed.

The February meeting was held at the Orange County Hospital on the 3d. The paper of the evening was read by M. L. Pindell of Santa Ana on the subject, "Some Indications for Roentgen Ray Therapy." A most instructive talk was given, and in conclusion a number of interesting roentgenograms were shown by the author.

The Santa Ana Clinical Society met at Ketner's Cafe

the evening of January 23. An interesting talk was given by Dr. H. H. Lissner of Los Angeles on "Observations on a Recent Trip to Eastern and European Clinics." Officers for the ensuing year were elected as follows: President, Bessie Stokes Martell; vice-president, Rowland P. Yeagle; secretary-treasurer, W. C. Dubois.

New members since the first of the year include J. Muncey Bulpitt and Zoe N. Bulpitt, formerly members of the Stanislaus County Society; Frank H. Paterson, transfer from the Santa Clara Society; and M. L. Pindell, transfer from the Madison County, Iowa, Society.

The society has recently lost one of its most active members, W. Leland Mitchell, County Health Officer. Dr. Mitchell came here some two years ago from the Rockefeller Foundation as the first full-time health officer in the county. During his stay he handled many difficult situations and established many needed institutions in the health department, including a very efficient laboratory with full-time workers at the County Hospital. He was recalled to New York by the parent organization the first of the year. His place has been taken by V. G. Presson, who has come here from Alabama.

SACRAMENTO COUNTY

Sacramento Society for Medical Improvement (reported by Bert L. Thomas, secretary)—The February meeting of the Sacramento Society for Medical Improvement was held at the Hotel Sacramento on the 17th. There were thirty-nine members in attendance. The minutes of the January meeting were read and approved.

Presentation of Cases—Schoff presented two patients with a most diffuse head and body distribution of trichophytosis. Both cases were of the licheniform type, and were in youngsters.

Brendel demonstrated two cases to show most satisfactory operative results. The first was of a broken back that came in paralyzed from the waist down. An immediate operation resulted in obtaining excellent function. The second was of a congenital deformity—an exceedingly motile vertebral inter-articulation—causing the patient to assume almost a crouch position. Spinal column bone-splints gave this man a most satisfactory working back.

Gundrum displayed some interesting snapshots of a patient only 18 months old who possessed a 5 cm. thyroid gland which was causing a typical exophthalmic goitre picture.

The speaker of the evening was Dr. Charles Schoff. His presentation of interesting skin cases was rendered through lantern slides. Schoff had recently returned from a number of skin clinics in the East, and the plates obtained there, together with those from his own large collection, gave to all present a most delightful skin clinic that could only have been surpassed by the presence of the patients themselves. Fay discussed the possible merits of proper surgery in early keloids. Zimmerman inquired about the types of epitheliomata amenable to surgery and x-ray. Schoff suggested that neither are used in the Skin and Cancer Hospital, but that radium is the only therapeutic agent applied here. Yates discussed a case that had come under his observation. The case was probably an actinic affair, and so would yield probably to mere covering of the parts.

Application for membership was received from Doctor Sanborn, the resident physician at Folsom prison. Dimit applications from Dr. James Thom, formerly of San Francisco, and from Dr. Richard Scribner, formerly of Hammon, were received. Both of these applications had been acted upon by the board of directors, and thus both were declared members of the local society.

The board of directors reported that the annual banquet to be held on March 17 was being taken care of by a committee comprised of Drs. Hale, Jones, Dunlap, Schoff, and Harris. Alanson Weeks of San Francisco will present the paper of the evening. They also reported that Dr. Pottenger of Monrovia will present a paper at the April meeting.

The board appointed Drs. Parkinson and Hall as a committee to revise the by-laws in accordance with those of the state, the secretary of the State Society suggesting those of the San Francisco County as a correct model.

A letter from the state secretary, Dr. Emma W. Pope, was read to the society, calling attention to the optional

medical defense offered by the State Society. Some confusion had arisen, since both the state dues and the fee for the optional defense were the same.

SAN DIEGO COUNTY

San Diego County Notes (reported by Robert Pollock)—During February the County Society presented two very interesting scientific programs. One, a clinical evening at the San Diego County General Hospital, with a program of unusual excellence furnished by members of the visiting and house staffs. The other meeting, a dinner session at the Cabrillo Restaurant, was addressed by Dr. Clarence G. Toland of Los Angeles, who gave a comprehensive and practical paper on surgery of the upper abdomen. Beginning his talk with a review of the nerve supply to the structures in this area, he constantly kept this before his audience in discussing symptoms and diagnosis. His talk was entertainingly illustrated by Dr. K. S. Davis, roentgenologist of St. Vincent's Hospital, Los Angeles, who showed a large series of x-ray plates illustrating various upper abdominal conditions. Discussion on the paper was opened by H. C. Oatman of San Diego and A. B. Smith, roentgenologist of the Scripps Memorial Hospital, La Jolla, after which the paper enjoyed a rather liberal general discussion by members of the society.

The society has accepted an invitation from Commander Owen of the Hospital Ship Relief to spend the evening of Saturday, March 14, on board ship, at which time an interesting scientific program will be presented by medical officers of the navy.

The recently elected officers of the medical staff of the San Diego County General Hospital are Clarence E. Rees, chairman; Louis Strahlmann, vice-chairman; and C. L. Stealy, secretary.

Things look promising for breaking ground during March for San Diego's first physicians' building, pictures of which, the so-called "Medical Arts Building," show a beautiful ten-story structure, admirably adapted for its purposes—that of housing exclusively physicians, dentists, and their necessary aids. This building will be placed at the corner of Eleventh and C streets, directly in line with the natural growth of the business district, and yet, for the time, slightly beyond the greatest traffic congestion.

SAN FRANCISCO COUNTY

St. Joseph's to Rebuild—Staff to Discuss Medical Economics—March 12 St. Joseph's Hospital staff and patronesses, San Francisco, met at dinner, offered by the Sisters, and advanced the drive for \$500,000 in April for the fire-proof reconstruction of the main buildings. Dr. A. S. Musante, head of the staff, represented the latter, and Mrs. W. T. Cummins was invited as president of the patronesses. Attorney Hugo Newhouse, leader in legal and financial circles, as the general chairman of the campaign committee, was the principal speaker. He spoke of the thirty-six years of service of the Sisters of St. Joseph's, which had always the lowest rates in the city, enabling self-reliant patients to pay their way through the wards for \$17.50 per week. The highest standing in standardization had been received from the American College of Surgeons, and the American Medical Association had endorsed the hospital for intern or fifth year for medical graduates. The school of nursing was accredited by the California State Board of Health. Mr. Newhouse reported upon two meetings held the previous Monday—one a luncheon of bankers and financial men, and the other a dinner of the heads of the different religious fraternities—and another to be held at the Palace Hotel the following Wednesday, composed of 300 of the prominent civic representatives. Archbishop Edward J. Hanna, honorary chairman, made stirring appeals at these gatherings and has entered actively into the drive.

At the crowded staff meeting on "Medical Economics," after the supper Attorney J. F. Denman spoke on "Principles in Handling Patients' Accounts." He distributed a page form with single-line entries of charges, receipts, date, name and address of patient and person responsible, service, and remarks, and another for a loose ledger page for posting each patient's financial data. Carelessness in necessary details concerning debtor, proper fees, sending bills, following up "skips" and referring to collector were exemplified. Legal claims against estates must be filed

within four months after death. A simple income tax sheet was also distributed. Doctors were urged to have their accounts attended to by others if they cannot give them the proper attention.

Percy A. Wood of the Wells Fargo Bank discussed "Fundamentals of Investments for Doctors," saying:

"Safety, marketability and rate of interest are the three factors in investments, and it is impossible to find all rank high in any one of them. For example, bonds of the United States Government have the greatest safety and marketability, as they can be sold any time without delay, but the rate of interest is less than a savings bank pays. Doctors cannot study the investment field, as few have the knowledge, time and means to do it right, and an investment banker must be consulted. He recommends after a critical study the use of his organization, expert staff, and financial resources. His feeling of responsibility continues till the bond (principal and interest) is paid. I suggest that you diversify your holdings, i. e., distribute your risks as much as possible so that they will be subject to different principles of fluctuation and the losses of one will be neutralized by the gains of another. Each investment should be a separate risk and independent of the forces influencing the hazard of any other investment you may have."

Irving H. Frank, manager of the hospital bond division of the National Surety Company, presented a paper on "Insurance—the Economics of Misfortune," abstracted as follows:

"Ancient Greeks started insurance by advancing money on ships, which was to be repaid with interest if the voyage was successful. Belgium, in the fourteenth century, had the first insurance with direct charge of premium. Insurances have improved and now, by paying a specified sum to a company, one can be insured against almost every possible loss. Large investments of companies tend towards better living conditions, which aid the individual. The latest form of insurance is the Hospital Bond, which up to the amount of coverage purchased, pays for bed and board, use of operating-room, anesthetic, x-ray and laboratory treatments, medicines, and ambulance in any hospital in the United States and Canada. CALIFORNIA AND WESTERN MEDICINE endorses it as protection for the patient and beneficial to the hospital and physician, as hospital expense is a big item in illness."

C. A. Mariani, manager of the Professional Men's Clerical Bureau, discoursed on "The Doctor as a Better Business Man," summarized below:

"The doctor as a business man is a failure, as attention to his profession makes it impossible for him to attend to his accounts properly. A competent aid is necessary. A doctor should have a plan for getting certain information when with the patient which can be used by his accountant. He must make with every call a record of the name, address, phone, and occupation of person to whom to charge the account; then the patient's name and address, reference and address, and get a copy of the hospital record of patients treated there, the name of a doctor calling him for a consultation or assistance in operation, as well as the history, and record the proper charge at the time of the service. He should make receipts in duplicate for payments and note how patients will pay. Collections must be requested on the same day monthly, and enforced after 120 days."

Drs. I. Gobar, Walter Smith, and H. Deering suggested a black list for dead-beats and prevention of imposition.

Southern Pacific General Hospital (reported by W. T. Cummins, secretary)—The regular monthly clinical meeting was held at the Southern Pacific General Hospital, Huntington Hall, on Wednesday, March 4, at 8:30 p. m.

L. B. Crow presented a paper on "Pulmonary Infarcts," in which he stated that this is a relatively common lung complication, and that it is frequently overlooked by the internist. As a sequel of major operations, it is much more frequently present than has been suspected, for it has been mistaken for pleurisy and pneumonia. Pulmonary congestion caused by any pathological condition favoring a slowing of the blood stream from the right ventricle favors infarction.

It is quite essential to correlate carefully the clinical and roentgen findings in every post-operative lung complication, so that a correct diagnosis may be made. All patients that show any pulmonary congestion following

major operations should be kept in bed and closely watched for a longer period of time than is customary, so as to avoid, if possible, any embolic complications. The paper was illustrated with numerous roentgen pictures, one series showing progressive resolution in an infarct.

J. H. O'Connor gave a roentgen-illustrated talk on "Closed Reduction of Comminuted Fractures." The technique, as applied to fractures of the lower extremity, is as follows:

A plaster cast is applied to the foot a few days before attempted reduction. The foot is well padded with sheet wadding, and over this a layer of thick felt is applied. In the cast there is incorporated part of a muslin bandage, leaving a loop to project from the sole of the foot. Reduction is effected under anesthesia, the pelvis being fixed by a skein of woolen yarn passing around the upper part of thigh of affected side and fixed by a hook in the wall back of the patient. Extension is made by a windlass in the wall at the foot of the patient. The wire from this is hooked to the protruding muslin loop incorporated in the cast so that proper traction may be maintained until the cast is sufficiently hardened. As a matter of safety the cast is then split down the center, for this will maintain the reduction as well as an unsplit one, and pressure sores will then be eliminated.

W. T. Cummins reviewed 274 of the General Hospital autopsies, and illustrated with charts 498 clinical and pathological conditions. A number of interesting cases were cited, such as ruptured aneurysms, dyspituitarism, dextrocardia, pulmonary abscesses, odiococcidioid disease, etc. He emphasized the importance of the intern's position in getting permission for autopsies, and regretted the lamentable apathy of many clinicians towards autopsies. He believes that there should be better co-operation of the clinician and the laboratory and, aside from the subject in hand, that the clinician should know a little more about the details of laboratory technique and preparation therefor, as exemplified in occult blood, examinations of stools and basal metabolism determinations.

Franklin Hospital Clinical Society (reported by Ewald H. Angerman, secretary)—The regular staff meeting of the Franklin Hospital Clinical Society was held March 2 at the hospital, Frank R. Dray presiding.

The paper of the evening was ably presented by William W. Washburn before a large audience. A resume of his talk follows:

This paper covered many of the more practical aspects of goiter surgery. A few minutes were taken during the early part of the reading of the paper to show slides from microscopic sections, illustrating clearly the various types of thyroid disease, giving one a definite pathological classification upon which the paper was based.

While it may be admitted that exophthalmic goiter or Basedow's disease is a self-limiting disease, one cannot predict the degree of toxicity which any given case may exhibit. Statistics based upon mortality rates from any line of treatment do not tell the whole truth, for the morbidity should be seriously considered in cases treated over a long period of time by medical measures.

A type history was read, illustrative of a case of Basedow's disease of moderate severity. The significance of various signs and symptoms were discussed, particularly laboratory data. Emphasis was laid upon the necessity of a careful consideration of these clinical signs and symptoms in weighing the degree of toxicity in a given patient. The basal metabolic rate, particularly when a single reading is taken, should be accepted only in a relative sense. When taken *in conjunction with other factors* the basal metabolic rate is an index of the intensity of the disease in all types of hyperthyroidism and is of great aid in selecting the best time for operation and the best type of surgical procedure. Exophthalmic goiters run a higher average basal metabolic rate than do toxic adenomas, yet a case of 60 plus may be a better surgical risk than one of exophthalmic goiter with a 30 plus rate, because of the greater likelihood of cardiovascular changes in the former type case. Hyperthyroidism from toxic adenoma should be carefully differentiated from that of Basedow's disease. Exophthalmos and a bruit over the gland is not gotten with adenomas unless there be an associated hyperplasia. All adenomas becoming toxic or giving pressure symptoms should be removed. Adenomas in patients over 40

years of age become malignant in over 2 per cent of cases. The importance of a pre-operative laryngoscopic examination in all adenomatous conditions was emphasized.

The full Kocher collar incision should be used, as it allows an exploration of the entire gland. Lugol's solution, as well as preliminary arterial ligations, is of great aid in preparing exophthalmic goiter patients for operation.

Improvement in method or means of preparing patients for thyroidectomy has resulted in a marked lowering of operative mortality rate.

A large number of lantern slides were shown at the conclusion of the paper.

Discussion by Falconer, Yoell, Bruck, Cook, Newall, Weil, Day, Taylor, and Quinn.

SAN MATEO COUNTY

San Mateo County Medical Society (reported by Dr. Callaway, secretary)—The regular monthly meeting of the San Mateo County Medical Society was held February 18 at the Community Hospital, in conjunction with the commission of the Community Hospital. This was the first annual meeting of the society with the hospital, and at this meeting a report of the commission was rendered showing the activities of the hospital during the past year. Talks were given by the Rev. Father Ramm on the commission form of government of county hospitals. Dr. W. P. Lucas of the University of California Hospital talked on hospital organization.

San Mateo County is indeed fortunate to have this new and beautifully equipped institution for the care of county patients, as well as full-pay and part-pay patients. The medical society of the county is supporting the institution with their services, and it has been a great means of cementing the society into an active organization.

Since the reorganization of the county society in June of 1923, we have met each month, except one, and at each meeting interesting cases have been presented by members of the society, or interesting talks have been given to us by physicians from San Francisco. It is indeed gratifying to see the interest that is now being shown in the society, and I trust that it will continue.

SANTA BARBARA COUNTY

Santa Barbara County Medical Society (reported by Alex C. Soper, Jr., secretary)—A joint meeting of the County Medical and Dental Societies was held at the University Club, succeeding a dinner there, at which fifty-two members and guests participated, the occasion being the presence of Dr. Henry S. Pritchett, president of the Carnegie Foundation, and Dr. F. V. Simonton, head of the Dental Research Laboratory at the University of California.

The meeting began at 8:45 p. m., Franklin Nuzum, president of the County Medical Society, in the chair. The following resolution was read by the secretary, and on motion duly passed, with an order that copies be sent to the daily press, the Carnegie Foundation, and the state association:

"WHEREAS, Over a period of years the medical and dental professions have viewed with increasing respect the constructive and progressive activity of the Carnegie Corporation and the Carnegie Foundation for the Advancement of Teaching, and

"WHEREAS, Of the executives concerned in this distinguished service, Dr. Henry S. Pritchett has always been outstanding, be it

"RESOLVED, That the Medical Society and the Dental Society of Santa Barbara County at this joint meeting record herewith their recognition of, and sympathy with, these services, and express to the Carnegie Corporation, the Carnegie Foundation for the Advancement of Teaching, and Dr. Henry S. Pritchett, their respect and appreciation."

Henry C. Bagby, M. D., D. D. S., introduced with some facetious remarks Dr. Simonton, who described at length the research work done at the University Dental Laboratories, with especial reference to pyorrhea and the hope of speedy solution of the problem.

Franklin R. Nuzum introduced Dr. Pritchett, who spoke upon the similar interests of the medical and dental pro-

fessions and the advisability of their greater co-operation and unity; compared the care of the diseases of the mouth with the care of those of the eye, nose, throat, etc., as specialties.

SANTA CLARA COUNTY

Santa Clara County Society (reported by Alson A. Shufelt, secretary)—The last regular meeting of the year for the Santa Clara County Medical Society was held December 17, 1924. Dudley Fagerstrom, E. L. Cottrell, C. H. Arnold, were elected to membership, and the resignation of C. E. Wintermute was accepted. The election of officers was then taken up, and the following elected for 1925: President, Doxey Wilson; first vice-president, J. B. Bullitt; second vice-president, Jonas Clark; third vice-president, J. H. Kirk; secretary, Alson Shufelt; assistant secretary, E. A. Turco; treasurer, B. E. Loehr. Councilors-at-large: F. S. Ryan, E. P. Cook, A. E. Fillipello. Delegates: J. H. Shepherd, D. A. Beattie. Alternates: C. E. Saunders, G. A. Barry.

The first meeting of 1925 was held January 21 at the Santa Clara County Hospital, with an attendance of forty members. After a short business meeting in which three new applications for membership were presented, and a few minor matters disposed of, the main program of the evening was presented. This was made up of demonstrations of clinical cases by the hospital staff. Clarke Saunders showed a case of a young man who was regaining his vision after total blindness from a luetic keratitis, discussing briefly the treatment and prognosis. Clement Arnold followed with two interesting neurological cases—one a post-influenza encephalitis of the typical Parkinsonian type; the other a spastic paraplegia in a young adult that had been present since birth with accompanying mental deterioration, and in which there was a question of differential diagnosis. Next, a case of lung abscess was discussed by George Gray, and a case of bronchiectasis in which pneumo-thorax had been tried without result, was shown by Louis Boonshaft. A report of the activities of the year at the County Hospital was then read by Dr. Doxey R. Wilson, after which he presented an unusual case of an ovarian tumor. This patient had known of its presence for many years, but had only recently applied for treatment. Eight gallons of fluid had been aspirated within a short time, but the tumor mass still present seemed to weigh more than the patient herself. (This was later proven true.) Henry Dahleen showed a case of ureteral stone with resultant kidney destruction. Demonstration of unusual pathological specimens by Dr. Proescher concluded the scientific part of the meeting. Refreshments were then served, and the meeting adjourned. It was an excellent program, and members not present really missed an opportunity.

The regular February meeting of the Santa Clara County Medical Society was held at the Commercial Club rooms on February 18, it being the annual dinner meeting. Over fifty members were present to enjoy an excellent dinner and a good program. Scientific subjects were more or less banned for the evening, and the time spent in friendly discussions and in a renewal of old relationships. It was pleasing to see several members from towns other than San Jose, and we only regret that there might not have been more. The speaker of the evening, J. Wilson Shiels of San Francisco, was presented by Doxey R. Wilson, and in his inimitable way delighted his audience with his humor, and with his reminiscences of the old-time practitioner and the "good old family doctor," whose passing he deeply regretted.

Before the meeting adjourned, it was entertained by a half-hour of magic by a deaf and dumb artist of rare talent.

SONOMA COUNTY

Sonoma County Medical Society (reported by G. A. Hunt, secretary)—The Sonoma County Medical Society met in Santa Rosa, March 12. Twenty-five members were present.

Samuel H. Hurwitz of San Francisco gave an excellent address on "The Treatment of Asthma."

A myxedema patient was presented by Doctors Cline and Bonar of Santa Rosa.

The establishment of a professional credit bureau in

connection with the Luce Adjustment Agency of Santa Rosa was discussed and voted on. The majority decided in favor of a credit bureau. From this bureau the professional credit standing of many patients that apply for treatment can be obtained.

✱

VENTURA COUNTY

Ventura County Medical Society (reported by C. F. Schultz, secretary)—At a meeting of the County Medical Society on January 19 the annual election took place. The 1924 officers were elected for another year; also the delegates and alternates to the state meeting.

Santa Paula's members had been present at all of the 1924 meetings, namely, Blaisdell, Merrill, and Schultz, and only one other member had a clean record, Bianchi of Ventura.

At the February meeting at Ventura, Verne Mason of Los Angeles presented a paper on abdominal tumors which proved very interesting.

The society anticipates a renewed interest in its meetings and programs for this year. The next meeting will be held at the Ventura Country Club on March 3.

✱

YOLO COUNTY

Yolo County Medical Society (reported by John D. Lawson, secretary)—A meeting of the Yolo County Medical Society was held on March 3 at the Woodland Clinic building. There were present, T. C. Cooper, W. E. Bates, W. J. Blevins, C. H. Fairchild, F. R. Fairchild, J. E. Harbinson, E. E. Larson, H. D. Lawhead, W. J. Spencer, L. P. Bell, J. D. Lawson. Visitors—H. M. Elberg, D. D. S., Shaffer, D. D. S., Pertins, D. D. S., and twenty members of the professional staff of Woodland Clinic.

E. Eric Larson of the Woodland Clinic spoke on "Ethylene Anesthesia"; L. P. Bell on "Regional Anesthesia"; and H. M. Elberg, D. D. S., on "Conduction Anesthesia."

E. Eric Larson of the Woodland Clinic surgical staff, a graduate of Rush Medical College, 1920, and Walter J. Spencer were elected to membership.

Walter J. Spencer has been added to the staff of the Woodland Clinic, assuming the chair of Pediatrics. Doctor Spencer is a graduate of Rush Medical College, 1916. He served in the navy during the war, since which time he has extensively studied children's diseases in various American clinics.

Since the last report the Woodland Clinic has had two talks open to the public at their regular monthly educational meetings. In January, L. P. Bell presented "Goiter" in a popular way. In February, E. Eric Larson gave a talk on "Indigestion." In March, W. J. Spencer spoke on "Preventable Diseases of Childhood." All of these presentations are made in lay language and are purely educational. The chief purpose is to instill into the minds of the layman the necessity of treatment by competent physicians and the utter lack of competence of the various "pathies."

CHANGES IN MEMBERSHIP

New Members—Robert K. Cutter, Eugene S. Maxson, Berkeley; Fred Ewing, H. O. Ellis, Szabo Kalman, John A. Dougherty, Charles E. Marquis, Oakland; Donald V. Burke, John J. Lalor Doyle, Chico; C. B. Cowan, Selma; Roland W. Dahlgren, Neil J. Dau, Gerald K. Nider, Fresno; C. S. Ambrose, F. L. Courley, John R. Brown, Herman Lando, Joseph N. Kolisch, Benjamin F. Hoyt, B. G. DuPre, Cecil Sutherland, W. Q. Harper, Fred Lindenberg, A. M. Hansen, Conrad I. Hubert, John Frederick Clark, Carl C. Cowin, Lars A. Dahl, John H. Hooval, Raymond W. Huntsberger, Wilma H. Jacobs, Mary L. Neff, Frances I. Richman, Ernest H. Ruediger, A. A. McClurkin, Los Angeles; George Wells, Bell; Guy L. Bliss, Long Beach; Fred L. Horton, Pomona; John L. Steffy, Santa Monica; Dean M. Walker, Sherman; George I. Dawson, Napa; J. Hudson Sale, Ernest K. Stratton, Sigurd von Christierson, F. H. Redewill, Dorothy W. Atkinson, Elizabeth A. Davis, Curtis E. Smith, Henry L. Wagner, San Francisco; H. L. Mawdsley, Frank Gehrels, San Mateo; William H. Murphy, Redwood City; Joseph D. Lewis, Santa Barbara; E. H. Eiskamp, Watsonville.

Transferred—Norman C. Paine, from Tulare County

to Los Angeles County; Horace A. Hall, from Riverside County to Los Angeles County; Frederick P. Shafer, from San Francisco County to Siskiyou County; Gwendolyn Stewart, from San Francisco County to Los Angeles County.

Resigned—Joseph Fife, Victor Randolph, Anna K. Davenport, San Francisco; Henry D. Rinehart, Herbert C. Jones, Pasadena; Robert E. Merritt, Leon W. Mansur, Frances C. Turley, Los Angeles; Robert C. Nichols, Ontario.

Retired—George Adam, San Francisco.

Honorary Members—A. Liliencrantz, Oakland; R. C. Shawhan, Soldiers' Home, Sawtelle; J. H. Utley, James S. Calder, Los Angeles; George B. Kalb, Monrovia.

Deaths—Cook, Francis Steven. Died at Hollywood, February 28, 1925, age 60. Graduate of the University of California Medical School, San Francisco, 1887. Licensed in California in 1888. Doctor Cook was a member of the Contra Costa County Medical Society, the California Medical Association, and the American Medical Association.

Eddy, George Sigel. Died at Los Angeles, March 8, 1925, age 63. Graduate of the University of Illinois College of Medicine, Chicago, 1896. Licensed in California in 1897. Doctor Eddy was a member of the Los Angeles County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Gourley, Frederick Lantz. Died at Los Angeles February 10, 1925, age 48. Graduate of the University of Illinois College of Medicine, Chicago, 1903. Licensed in California in 1920. Doctor Gourley was a member of the Los Angeles County Medical Society, the California Medical Association, and a Fellow of the American Medical Association.

Mitchell, William Leland. Died at Santa Ana, February, 1925. Graduate of the Washington University Medical School, St. Louis, Mo., 1918. Licensed in California in 1923. Doctor Mitchell was a member of the Orange County Medical Society, the California Medical Association, and the American Medical Association.

The Price—Winning a prize from life is like gathering a crop from the garden. Unless we dig deep, putting our backs into the job, unless we feed the soil, and sow and water, weed and cultivate, rise early and stay out late to guard what we planted, unless we ache with the labor of its growing, we never harvest the crop of our dreams. We have not paid in full.—Angelo Patri.

STIMULANTS, DEPRESSANTS, HUMOR

"I do appreciate very much your interest in my article. This labor on your part must be the cause of the excellence of your journal. In changing the paper along the lines of your suggestion, I have also shortened it several pages."—Los Angeles.

In Three Generations

Teacher—Jimmie, define and give an example of heredity.

Jimmie—It means that—that—that if your grandfather didn't have no children your father wouldn't have none neither—and neither would you.

Jakie—Ikey, you should put the curtains down when you kiss your wife; I saw you last night.

Ikey—The chokes on you, Jackie; I wasn't home last night.

There Are Pioneers, Plodders, and Parasites

Pioneers make the venture and the conquest. Plodders consolidate and hold what has been gained. Parasites follow to live off others' labors. Each fulfills a purpose, even the parasite. He is pretty low down in the scale, like the maggot, but his presence is an advertisement that something exists on which he can live. It is likewise a warning that that "something," whatever it may be, should be eliminated.

Now that the glands are the fashion as a panacea for every ill or want, why not give the sweat glands a good tryout and see what happens?—San Diego Union.

PROGRAM

THE FIFTY-FOURTH ANNUAL SESSION
OF THE CALIFORNIA MEDICAL ASSOCIATION TO BE HELD
AT YOSEMITE NATIONAL PARK, CALIFORNIA, MAY
18, 19, 20, 21, 1925

OFFICERS AND COMMITTEES, 1925

Granville MacGowan, Los Angeles, President.
Edward N. Ewer, Oakland, President-Elect.
Harry E. Alderson, San Francisco, Vice-President.
Emma W. Pope, San Francisco, Secretary.
W. E. Musgrave, San Francisco, Editor.
Hartley F. Peart, San Francisco, General Counsel.
Hubert T. Morrow, Los Angeles, Assistant General Counsel.
William H. Barry, Superintendent of Publications.

COUNCILORS

First District—Lyell C. Kinney, San Diego (1927)—San Diego, Riverside, Orange, San Bernardino, and Imperial Counties.

Second District—William H. Kiger, Los Angeles (1925)—Los Angeles, Santa Barbara, Ventura, and Kern Counties.

Third District—T. C. Edwards, Salinas (1926)—San Luis Obispo and Monterey Counties.

Fourth District—Fred R. DeLappe, Modesto (1925)—Fresno, Kings, Tuolumne, Merced, Mariposa, Madera, Tulare, and Stanislaus Counties.

Fifth District—David A. Beattie, San Jose (1926)—Santa Clara, San Mateo, San Benito, and Santa Cruz Counties.

Sixth District—Walter B. Coffey, San Francisco (1926)—San Francisco County.

Seventh District—Dudley A. Smith, Oakland (1926)—Alameda, Contra Costa, San Joaquin, and Calaveras Counties.

Eighth District—James H. Parkinson, chairman, Sacramento (1925)—Sacramento, Amador, El Dorado, Alpine, Placer, Nevada, Yuba, Sutter, Sierra, Yolo, Butte, Plumas, Lassen, Mono, Inyo, Glenn, Colusa, Tehama, Shasta, Modoc, and Siskiyou Counties.

Ninth District—James H. McLeod, Santa Rosa (1926)—Marin, Sonoma, Lake, Mendocino, Solano, Napa, Del Norte, Humboldt, and Trinity Counties.

Councillors-at-Large—O. D. Hamlin, Oakland (1925); Rene Bine, San Francisco (1926); George H. Kress, Los Angeles (1926); William T. McArthur, Los Angeles (1926); Morton R. Gibbons, San Francisco (1927); C. L. Curtiss, Redlands (1926).

DELEGATES AND ALTERNATES TO A. M. A.

Delegates—Victor G. Vecki, San Francisco (1926); Hans Lisser, San Francisco (1926); Albert Soiland, Los Angeles

(1927); Robert V. Day, Los Angeles (1927); Lemuel P. Adams, Oakland (1927).

Alternates—C. Van Zwahlenburg, Riverside (1926); William E. Stevens, San Francisco (1926); Charles D. Lockwood, Pasadena (1927); Robert Pollock, San Diego (1927); O. D. Hamlin, Oakland (1927).

COMMITTEES

Committee on Scientific Program—Emma W. Pope, chairman; Lemuel P. Adams, Oakland (1926); F. M. Pottinger, Monrovia (1927); Joseph Catton, San Francisco (1928); Walter V. Brem, Los Angeles (1925).

Committee on Arrangements—James H. Parkinson, chairman; Rene Bine, T. C. Edwards, Clinton D. Collins, Joseph K. Smith.

Executive Committee—Rene Bine, chairman; Granville MacGowan, Edward N. Ewer, Harry E. Alderson, James H. Parkinson, Emma W. Pope, W. E. Musgrave, Hartley F. Peart.

Auditing Committee—Rene Bine, chairman; Morton R. Gibbons.

Committee on Bunnell Memorial—Emmet Rixford, chairman; Saxton T. Pope, Egerton Crispin.

Publicity for 1925 State Meeting—Celestine J. Sullivan.

GENERAL HEADQUARTERS AND MEETING HALLS

Diagrammatic map, showing location of various offices and meeting halls, will be distributed at Registration and Information desks. See also diagram, page 472.

- (A) Secretary's office—Council Room, Lodge.
- (B) Registration Bureau—Lodge Registration Office.
- (C) Information offices—Lodge Registration Office; Sentinel Hotel Lobby in Village; Lobby at Camp Curry.
- (D) Consolidated Ticket office—Transportation office at Lodge.
- (E) Publicity Committee—Advertising room in Village.
- (F) Council Room—Lodge.

- 1. Tent, seats 800 located in Lodge.
 - 2. Government Pavilion, seats 400, located in Village.
 - 3. Pillsbury Pavilion, seats 300, located on Lodge side.
 - 4. Dining room, Sentinel Hotel, seats 150, located in Village.
 - 5. Antler's Club, seats 75, located back of church in Village.
 - 6. Sentinel Lobby, seats 100, located in Village.
 - 7. Pillsbury Studio, seats 100, located in Village.
- (Letters and figures refer to locations shown on the map.)

DIAGRAM OF MEETINGS									
(In case of inclement weather, General Sessions will be held in Government Pavilion, Village)									
		Tent	Government Pavilion	Pillsbury Pavilion	Sentinel Dining Room	Antler's Club	Sentinel Lobby	Pillsbury Studio

	2-4:30	Industrial Medicine	General Medicine	Obstetrics	Neuropsychiatry				

GENERAL OUTLINE OF THE MEETINGS

There will be three sessions on Monday, Tuesday and Wednesday, and two sessions on Thursday.

Uniform hours for all meetings are provided for 10 a. m. to 12:30 p. m.; 2 to 4:30 p. m., and 8 to 10 p. m.

The time of each meeting is shown in the diagram.

General Sessions—Two general sessions open to members and guests will be held on Monday and Thursday mornings.

Bunnell Memorial—The unveiling of the plaque to Doctor Lafayette Houghton Bunnell at the foot of El Capitan with appropriate ceremonies will be held on Tuesday morning. Automobiles leave the Lodge Porch at 10 a. m.

Section on Medical Economics, Education, Public Health and Hospitals—This meeting is held under the auspices of the League for the Conservation of Public Health on Wednesday morning.

The Medical Society of the State of California (Optional Defense Group)—All members of the California Medical Association and guests are invited to attend this meeting, which will be held Tuesday evening.

The following sections will hold meetings:

Anesthesiology.
Dermatology and Syphilology.
Eye, Ear, Nose and Throat.
General Medicine.
General Surgery.
Industrial Medicine and Surgery.
Neuropsychiatry.
Obstetrics and Gynecology.
Pathology and Bacteriology.
Pediatrics.
Radiology, Roentgenology and Radium Therapy.
Technical Specialties.
Urology.

Council Meetings

First Meeting—Sunday, May 17, at 8 p. m.
Second Meeting—Monday, May 18, at 2 p. m.
Third Meeting—Tuesday, May 19, at 2 p. m.
Fourth Meeting—Wednesday, May 20, at 2 p. m.
Fifth Meeting—Thursday, May 21, at 2 p. m.

Meetings of the Council With the Presidents and Secretaries of Constituent Societies

All members of the Council and all presidents and sec-

retaries and assistant secretaries of constituent societies are requested to be present at a luncheon to be held in the Porch Dining Room of the Sentinel Hotel, Yosemite Village, on Tuesday, May 19, at noon.

HOUSE OF DELEGATES

Membership

Councilors—First District, Lyell C. Kinney (1927); Second District, William H. Kiger (1925); Third District, T. C. Edwards (1926); Fourth District, Fred R. DeLappe (1925); Fifth District, David A. Beattie (1926); Sixth District, W. B. Coffey (1926); Seventh District, Dudley A. Smith (1926); Eighth District, James H. Parkinson (1925); Ninth District, James H. McLeod (1926).

Councilors-at-Large—O. D. Hamlin (1925), Rene Bine (1926), George H. Kress (1926), William T. McArthur (1926), Morton R. Gibbons (1927), C. L. Curtiss (1926).

Ex-Officio—President Granville MacGowan, President-Elect Edward N. Ewer, Vice-President Harry E. Alderson.

FIRST MEETING OF HOUSE OF DELEGATES

Tent, Lodge, Monday, May 18, at 8 p. m.

Order of Business

1. Calling to Order.
2. Roll Call.
3. Report of President.
4. Appointment of the Reference Committee by the President.
5. Report of the Council, James H. Parkinson, chairman (presented before the General Sessions).
6. Report of the Committee on Scientific Program, Emma W. Pope, chairman.
7. Report of the Auditing Committee, Rene Bine, chairman.
8. Report of Committee on Bunnell Memorial, Emmet Rixford, chairman.
9. Report of Secretary, Emma W. Pope.
10. Report of Editor, W. E. Musgrave (presented before General Sessions).
11. Unfinished Business.
12. New Business.
13. Reading and Adoption of Minutes.
- Adjourment.

SECOND MEETING OF HOUSE OF DELEGATES

Tent, Lodge, Wednesday, May 20, at 8 p. m.

Order of Business

1. Calling to Order.
 2. Roll Call.
 3. Announcement of the Place of Meeting, 1926.
 4. Election of Officers:
 - (a) Election of President-Elect.
 - (b) Election of Vice-President.
 - (c) Election of Councilors.
- Second District**—Incumbent, William H. Kiger, Los Angeles (1925)—Los Angeles, Santa Barbara, Ventura, and Kern Counties.
- Fourth District**—Incumbent, Fred R. DeLappe, Modesto (1925)—Fresno, Kings, Tuolumne, Merced, Mariposa, Madera, Tulare, and Stanislaus Counties.
- Eighth District**—Incumbent, James H. Parkinson, Sacramento (1925)—Sacramento, Amador, El Dorado, Alpine, Placer, Nevada, Yuba, Sutter, Sierra, Yolo, Butte, Plumas, Lassen, Mono, Inyo, Glenn, Colusa, Tehama, Shasta, Modoc, and Siskiyou Counties.
- Councilor-at-Large**—Incumbent, O. D. Hamlin, Oakland (1925).
- (d) Election of Member on Program Committee (four years)—Incumbent, Walter V. Brem, Los Angeles (1925).
 - (e) Confirmation of Election by Council of Hans

Lisser, San Francisco, to replace T. C. Edwards, Salinas (1926), resigned Delegate to A. M. A.

(f) Confirmation of Election by Council of three Delegates to A. M. A. needed to complete five authorized—Albert Soiland, Los Angeles (1927); Robert V. Day, Los Angeles (1927); Lemuel P. Adams, Oakland (1927).

(g) Confirmation of Election by Council of three Alternates to A. M. A. needed to complete five authorized—Charles D. Lockwood, Pasadena (1927); Robert Pollock, San Diego (1927); O. D. Hamlin, Oakland (1927).

5. Report of Reference Committee.
 6. Presentation of President.
 7. Presentation of President-Elect.
 8. Reading and Adoption of Minutes.
- Adjournment.

GENERAL INFORMATION

General Sessions—In case of inclement weather, General Sessions scheduled for the Lodge Tent will be held in the Government Pavilion, Yosemite Village, and other changes will be announced at the General Sessions.

Registration and Information—The registration and information desk is located at Yosemite Lodge. All persons attending the Convention, whether members or not, are requested to register immediately on arrival. Beginning Sunday, May 17, registration secretaries will be on duty daily from 9 a. m. until 4 p. m.

Guests and Visitors—All guests and visitors are requested to register. All General Sessions and scientific meetings are open to visitors and guests.

Badges—Four kinds of badges will be issued by the registration bureau. Members: Only active, associate, affiliate or honorary members of the California Medical Association will be issued the usual membership badge. Guest: A special badge will be issued to all fraternal delegates, visiting physicians, physiotherapists, medical social workers, nurses and other technical specialists who are attending the meetings upon official invitation of the Association. Delegates and Alternates: The usual official badge is provided for this purpose and will be issued to all persons authorized to wear it. Councilors: An official badge is provided for all members of the Council.

Membership Cards—Every member in good standing in the California Medical Association has been issued an official membership card for 1925. This card may be useful in connection with railroad tickets, and all members are requested to have their cards with them.

Suggestions and Constructive Criticism—The officers and committees have tried to do everything possible to make the meeting a success. Suggestions and constructive criticism calculated to make future meetings more useful will be welcomed by any of the officers. Complaints of whatever character should be made to the Registration Desk, where they will receive attention.

Social Program—No set social program has been arranged. The unusual attractions of Yosemite are believed to make this inadvisable. It is hoped that members and guests will form their own social contacts for sports, dinners, hiking and visits to places of interest. The program has been arranged so as to allow much time for amusement and recreation. There are no meetings before 10 a. m. and none between 12:30 and 2 p. m., and none between 4:30 and 8 in the evening.

Hospital—The Yosemite Hospital is located near Yosemite Lodge. Dr. Claude H. Church, who is in charge of the hospital, states that physicians and nurses are on duty at all hours.

Bus Line—The Yosemite Transportation System will maintain an adequate "street car" service between all meeting places of the various sections and the various hotels, including Camp Curry and the Lodge.

Press Representatives—Accredited press representatives are welcome and they will be accorded every possible courtesy.

Publicity—All publicity is in the hands of the Publicity Committee. It is requested that all persons having matter of "news" value report it to this committee. It is particularly requested that all "news" about any phase of the Convention be given out through the official committee and in no other way.

Exhibits—After mature deliberation by the Council and the Executive Committee it has been decided that no exhibits will be authorized. Accredited representatives of firms recognized in the advertising columns of California and Western Medicine will be accepted as accredited visitors to the Convention and authorized to solicit members and guests. Exhibits by all such representatives will be located in Oak and Cedar Cottages in Yosemite Village.

Rules Regarding Papers and Discussions at the State Meeting—Upon recommendation of the Executive Committee the following rules regarding papers have been adopted by the Council:

1. The maximum time that may be consumed by any paper is fifteen minutes, provided that not to exceed ten minutes' latitude may be allowed invited guests at the discretion of the presiding chairman.
2. Motions from the floor to extend the time of an author may not be entertained by the presiding officer.

3. The maximum time permitted any individual discussant on any paper is four minutes. This also applies to the author in closing his discussion. No discussant may speak more than once upon the same subject.

4. A copy of each and every paper presented at the State meeting must be in the hands of the chairman or secretary of the section or in the hands of the general secretary before the paper is presented.

5. Manuscripts not accepted by the Executive Committee for publication in the Journal will be returned to the author as soon as practicable. Authors desiring to publish their paper elsewhere than in the Journal may have their manuscript returned to them upon written request to the State Secretary.

6. No paper will be accepted by the General Program Committee nor by Section Program Committees unless accompanied by a synopsis of not to exceed fifty words.

7. Papers shall not be "read by title."

8. No member may present more than one paper at any one State meeting, provided that members may present additional papers before Sections on Technical Specialties; and provided further, that a member may be a collaborator on more than one paper, if these papers are presented by different authors.

9. Failure on the part of an author to present a paper precludes acceptance of future papers from such author for a period of two years, unless the author explains to the satisfaction of the Executive Committee his inability to fulfill his obligation.

FIRST GENERAL SESSION

GRANVILLE MACGOWAN, M.D., President,
Brack Shops Building, Los Angeles.

EMMA W. POPE, M.D., Secretary,
1016 Balboa Building, San Francisco.

Tent, Lodge, Monday, May 18, 10 a. m.

1. *President's Annual Address*—Granville MacGowan, M.D., Brack Shops Building, Los Angeles.
2. *Address of President-Elect*—Edward N. Ewer, M.D., 251 Moss Avenue, Oakland.
3. *Annual Report of the Council*—James H. Parkinson, M.D., chairman, 1601 I Street, Sacramento.
4. *Report of the Editor*—W. E. Musgrave, M.D., 806 Balboa Building, San Francisco.
5. *Report of the Legal Department*—Hartley F. Peart, General Counsel, 514 Humboldt Bank Building, San Francisco.

SECOND GENERAL SESSION

GRANVILLE MACGOWAN, M.D., President,
Brack Shops Building, Los Angeles.

EMMET RIXFORD, M.D., Chairman,
1795 California Street, San Francisco.

Dedication of Lafayette Houghton Bunnell
Memorial

Foot of El Capitan, Tuesday, May 19, 10 a. m.

Automobiles conveying members to the dedication ceremony will leave Yosemite Lodge at 10 a. m., headed by officers of the California Medical Association and invited guests.

1. *Introductory Speech and Unveiling of Plaque to Doctor Lafayette Houghton Bunnell*—Granville MacGowan, M.D., President California Medical Association, Brack Shops Building, Los Angeles.
2. *Address*—Mr. W. B. Lewis, Superintendent Yosemite National Park.
3. *Explorers in the Sierras*—Francis Farquhar, Sierra Club, San Francisco.
4. *Doctor Lafayette Houghton Bunnell*—Emmet Rixford, M.D., Chairman Committee on Bunnell Memorial, 1795 California Street, San Francisco.

THIRD GENERAL SESSION**Medical Economics, Education and Hospitals**

This Meeting Is Under the Auspices of the League
for the Conservation of Public Health

DUDLEY SMITH, M. D., President,
Oakland.

W. T. McARTHUR, M. D., Secretary,
Los Angeles.

Open to the Public and to all Members of the
California Medical Association

Tent, Lodge, Wednesday, May 20, 10 a. m.

1. *What the League Is Doing*—Dudley Smith, M. D., President League for the Conservation of Public Health.
2. *What Does the Public Want?*—William Duffield, M. D., Los Angeles.
3. *Advertising That Preys*—Celestine J. Sullivan.
4. *What Does the Medical Profession Want?*—W. B. Coffey, M. D., San Francisco.
5. *Science Versus Ignorance*—Dr. David Starr Jordan, President Emeritus Stanford University.

FOURTH GENERAL SESSION

Tent, Lodge, Thursday, May 21, 10 a. m.

1. *A Discussion of Some of the Problems Relating to the Symptomatology, Prognosis and Treatment of Arteriosclerosis and Arterial Hypertension*—John Phillips, M. D., Assistant Professor of Therapeutics, Western Reserve University; Associate Visiting Physician, Lakeside Hospital, and Directory of Medicine, Cleveland Clinic, Cleveland, Ohio.
2. *The History and Problems of Disease*—Walter V. Brem, M. D., 932 Maltman Avenue, Los Angeles.
3. *The Importance of Prognosis in Surgery*—Roland E. Skeel, M. D., Westlake Professional Building, Los Angeles.

THE MEDICAL SOCIETY OF THE STATE OF CALIFORNIA

(Sub-organization of the California Medical Association organized in June, 1923, to eradicate conditions giving rise to malpractice actions, and to further the protection of its members in such actions.)

JAMES H. PARKINSON, M. D., Chairman,
1601 I Street, Sacramento.

EMMA W. POPE, M. D., Secretary,
1016 Balboa Building, San Francisco.

Pillsbury Pavilion, Lodge, Tuesday, May 19, 8 p. m.

1. Chairman's Address: *The Organization and Purposes of The Medical Society of the State of California*—James H. Parkinson, M. D., 1601 I Street, Sacramento.
2. *The Doctor in Court*—Address by Hon. George F. McNoble, President California State Bar Association, Farmers and Merchants Bank Building, Stockton.

ANESTHESIOLOGY SECTION

J. ROBERT BURROWS, M. D., Chairman,
2305 Sacramento Street, San Francisco.

LOUISE A. OLDENBOURG, M. D., Secretary,
3032 Colby Street, Berkeley.

MEETING

Pillsbury Studio, Village, Monday, May 18, 2 p. m.

1. Chairman's Address: *Teamwork*—J. Robert Burrows, M. D., 2305 Sacramento Street, San Francisco. Secretary's Report.

2. Election of Section Officers and Transaction of Other Section Business.
3. *Nitrous Oxide and Regional Anesthesia in Abdominal Surgery*—P. K. Gilman, M. D., 350 Post Street, San Francisco.
4. *Cardiac Decompensation in Pregnancy*—Karl L. Schaupp, M. D., 516 Sutter Street, San Francisco.
5. *Local Anesthesia in Abdominal Surgery*—H. A. L. Ryfkogel, M. D., 516 Sutter Street, San Francisco; E. Carlson, M. D., San Francisco Hospital, San Francisco.
6. *Collaborating on the Effects of Impurities Often Present in Nitrous Oxide*—William Hutchinson, M. D., Detwiler Building, Los Angeles; Donald E. Baxter, M. D., 910 North Brand Boulevard, Glendale.

PACIFIC COAST ASSOCIATION OF ANESTHETISTS

Joint meeting with the Section on Anesthesiology of the
California Medical Association

CAROLINE B. PALMER, M. D., President,
2401 Sacramento Street, San Francisco.

ELEANOR SEYMOUR, M. D., Secretary,
845 West Tenth Street, Los Angeles.

FIRST MEETING

Pillsbury Studio, Village, Tuesday, May 19, 2 p. m.

1. Presidential Address: *Medication in Conjunction With Anesthesia*—Caroline B. Palmer, M. D., 2401 Sacramento Street, San Francisco.
2. *Evaluation of the Surgical Risk*—F. F. Gundrum, M. D., Capital National Bank Building, Sacramento; J. B. Harris, M. D., Capital National Bank Building, Sacramento.
3. *The Handling of Goitre Cases Demanding Surgery*—V. R. Mason, M. D., Pacific Mutual Building, Los Angeles; C. T. Sturgeon, M. D., 1136 West Sixth Street, Los Angeles.
4. *The Psychological Aspect of the Prospective Patient—and Special Reference to Pressure Induction*—Frank W. Chandler, D. D. S., Hollywood.
5. *Indications for General Anesthesia in the Extraction of Deciduous Teeth*—Evangeline Jordan, D. D. S., Los Angeles.
6. *Economies to be Effected in the Efficient Administration of Nitrous Oxide*—Donald E. Baxter, M. D., 910 North Brand Boulevard, Glendale.

SECOND MEETING

Pillsbury Studio, Village, Wednesday, May 20, 2 p. m.

1. *The Influence of Pre-operative Administration of Sugar in Acidosis*—Edgar I. Leavitt, M. D., 184 Forest Side Avenue, San Francisco.
2. *Preparation of the Diabetic for Surgery*—Horace J. Hagen, M. D., Santa Barbara.
3. *A Study of the Endocrines in Relation to Operative and Anesthetic Risk*—Clifford A. Wright, M. D., 2417 South Hope Street, Los Angeles.
4. *Blood Changes in Chronic Alcoholism—Their Similarity to Those Occurring in Chloroform and Ether Narcosis*—F. R. Nuzum, M. D., Cottage Hospital, Santa Barbara.
5. *Carbon Dioxide Method of De-Etherization*—Ethel Righetti, M. D., 305 Walnut Street, San Francisco.
6. *What is the Present Day Attitude of the Medical Profession Toward the Anesthetist?*—Jean Martin, M. D., 190 Twenty-seventh Avenue, San Francisco.

DERMATOLOGY AND SYPHILOLOGY SECTION

GEORGE DE WITT CULVER, M. D., Chairman,
323 Geary Street, San Francisco.

HIRAM E. MILLER, M. D., Secretary,
380 Post Street, San Francisco.

FIRST MEETING

Antler's Club, Village, Monday, May 18, 2 p. m.

1. Chairman's Address and Secretary's Report.
2. *Treatment of Poison-Oak Dermatitis*—Harry E. Alderson, M. D., 240 Stockton Street, San Francisco.
Discussion opened by W. G. Donald, M. D., 2251 Telegraph Avenue, Berkeley.
3. *Trichophytosis of the Glabrous Skin as a Clinical Problem*—Moses Scholtz, M. D., Brockman Building, Los Angeles.
4. *Vincent's Angina—The Significance of Fusiform Bacilli and Vincent's Spirochetes in Mucous Membrane Lesions*—Hiram E. Miller, M. D., 380 Post Street, San Francisco; Norman Epstein, M. D., University of California Hospital, San Francisco.
5. *Favus*—Kendal P. Frost, M. D., Pacific Mutual Building, Los Angeles; George F. Koetter, M. D., Pacific Mutual Building, Los Angeles.

SECOND MEETING

Antler's Club, Village, Tuesday, May 19, 8 p. m.

1. *Electro-Coagulation and Electro-Dessication as a Means of Destroying Malignant and Benign Skin Lesions*—Ernest K. Stratton, M. D., 350 Post Street, San Francisco.
2. *Treatment of Skin Cancer*—Edwin D. Ward, M. D., 361½ South Columbia Avenue, Los Angeles.
3. *Acne Vulgaris*—Charles E. Schoff, M. D., Farmers and Merchants Bank Building, Sacramento.
4. *Skin Diseases in Twins*—Thomas J. Clark, M. D., Oakland Bank of Savings Building, Oakland; Frank H. Stibbens, M. D., Oakland Bank of Savings Building, Oakland.

THIRD MEETING

Antler's Club, Village, Wednesday, May 20, 10 a. m.

Symposium on Treatment of Syphilis

1. Election of Section Officers and Transaction of Other Section Business.
2. *Sulpharsphenamine—Indications for Its Use and Technic of Intramuscular Injection*—Irwin C. Sutton, M. D., Taft Building, Hollywood.
3. *The Present Status of Bismuth in Anti-Syphilitic Treatment*—Samuel Ayres, M. D., 2007 Orange Street, Los Angeles.
4. *Therapeutics of Syphilis*—Howard Morrow, M. D., 380 Post Street, San Francisco.

Discussion on Symposium to be opened by LeRoy H. Briggs, M. D., 380 Post Street, San Francisco; Ernest D. Chipman, M. D., 391 Sutter Street, San Francisco.

EYE, EAR, NOSE, AND THROAT SECTION

ERNEST W. FLEMING, M. D., Chairman,
Pacific Mutual Building, Los Angeles.

PERCIVAL DOLMAN, M. D., Secretary,
Flood Building, San Francisco.

FIRST MEETING

Sentinel Dining-room, Village, Monday, May 18,
8 p. m.

1. Chairman's Address and Secretary's Report.
2. *Epinephrin in Glaucoma*—Kaspar Pischel, M. D., 135 Stockton Street, San Francisco.
3. *Studies in Ocular Dominance*—Lloyd Mills, M. D., Citizens National Bank Building, Los Angeles.
4. *A Study of the Sighting Eye in Young Children*—Percival Dolman, Flood Building, San Francisco.

SECOND MEETING

Sentinel Dining-room, Village, Tuesday, May 19,
2 p. m.

1. *The Correction of External Nasal Deformities (Lan-*

tern Slides)—J. D. Lewis, M. D., San Marcos Building, Santa Barbara.

2. *Treatment of Cicatricial Stenosis of the Larynx*—Simon Jesberg, M. D., 1151 West Sixth Street, Los Angeles.
3. *Primary Carcinoma of Middle Ear With X-ray Progressive Study*—Frank Albert Burton, M. D., Watts Building, San Diego.
4. *Pregnancy as a Complicating Factor in Ear Infection (Report of a Case)*—Harold A. Fletcher, M. D., 135 Stockton Street, San Francisco.

THIRD MEETING

Sentinel Dining-room, Village, Wednesday, May 20,
2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *Value of Visual Field Findings in Cranial Injuries*—Theodore C. Lyster, M. D., 1920 Orange Street, Los Angeles.
3. *Present Status of the Mechanism of Accommodation as Confirmed by Experimental Data*—P. Obarrio, M. D., 350 Post Street, San Francisco.
4. *Technique of a Safer Method of Cataract Extraction*—Otis Allen Sharpe, M. D., 516 Sutter Street, San Francisco.

GENERAL MEDICINE SECTION

ERNEST S. DU BRAY, M. D., Chairman,
Flood Building, San Francisco.

ROY E. THOMAS, M. D., Secretary,
1136 West Sixth Street, Los Angeles.

FIRST MEETING

Government Pavilion, Village, Monday, May 18,
2 p. m.

1. *The Triple Syndrome Affecting Blood, Digestive and Nervous Systems*—Alfred C. Reed, M. D., 380 Post Street, San Francisco; Harry A. Wyckoff, M. D., Stanford University Medical School, San Francisco.
The syndrome consists of a toxemia affecting: 1. Gastro-intestinal tract, tending toward atrophy, exemplified in sprue. 2. Blood system, tending toward pernicious anemia. 3. Nervous system, consisting of progressive combined degeneration of the postero-lateral tracts. All systems are affected, but with a wide variation of intensity. Etiology lies in protein poisoning or blood infection. Illustrated by cases.
2. *Sickle Cell Anemia (Lantern Slides)*—Gordon E. Hein, M. D., 1225 Bay Street, San Francisco; Randolph McCalla, M. D., San Francisco Hospital, San Francisco; George W. Thorne, San Francisco Hospital, San Francisco.

A male negro, aged 20 years, whose mother had the latent phase of sickle cell anemia, was observed in the active phase of the same condition. What constitutes the clinical picture. Are the joint and muscle pains, the epigastric pain, the fever, the slightly enlarged heart with a systolic murmur, the presence of gall-stones to be interpreted as part of the disease, or are they complications? X-ray evidence suggests duodenal ulcer. How is it to be interpreted? A compilation of the symptoms and signs (exclusive of the blood findings) of the published active cases is presented. Observations of the blood at different periods in the course, particularly during exacerbations and remissions, were made. A few of the factors influencing the sickling were studied.

3. *The Treatment of Nephritis*—James W. Sherrill, M.D., La Jolla.

The correlation between renal function tests and clinical findings in nephritis; changes in water balance in nephritis; hyperfunction in early renal lesions; renal function and changes in blood chemical

constituents; red cell volume and water balance in experimental partial nephrectomies.

4. *The Values of Gastro-Intestinal Motor Indices* (Lantern Slides)—Quinter O. Gilbert, M. D., Medical Building, Oakland.

Visceral symptoms arise largely from involuntary muscle disturbance. The symptomless abdomen has a rhythmic, orderly movement of contents, with a definite time sequence. Gastro-intestinal contents at the wrong place at the wrong time gives rise to local and reflex motor phenomena. A disturbance at one point influences the motility of the rest of the tract. The correct interpretation of these changes suggests the proper medical and surgical treatment. With a standard, fixed method of study, these changes may be expressed in a motor index formula.

5. *Diffuse Gastric Polyposis*—Four Cases (Lantern Slides)—Harold Brunn, M. D., 380 Post Street, San Francisco; Felix L. Pearl, M. D., 380 Post Street, San Francisco.

An analysis of fifty cases of diffuse polyposis of the stomach; this being a survey of all the cases reported in literature to date, with an additional report of four cases from the surgical service of the University of California Medical Department, three of which were operated upon by one of us. The analysis includes statistics of incidence, symptoms and signs, pathological anatomy, diagnosis and surgical treatment, supplemented by discussions of the history, etiology, and prognosis of the disease.

6. *Clinical Picture of Beginning Carcinoma of the Stomach (With Animadversions on the Radiological Illustrations in Gastro-Intestinal Diseases)*—Harry I. Wiel, M. D., 135 Stockton Street, San Francisco.

History and clinical picture given of a patient who was operated upon and after pathological examination of tissues showed an actual incipient carcinoma of the stomach. As far as we can find, it showed the earliest stage of carcinoma of the stomach that has been seen and followed clinically and surgically. Comparison between the clinical picture of earliest carcinoma of stomach as evidenced by this patient and the usual picture of carcinoma of stomach which is always full-blown by the time we diagnose. The x-ray findings in this case are of interest out of the routine and lead to reflections on similar radiological experiences in other patients with gastro-intestinal diseases. Remarks as to the conclusiveness of positive x-ray findings in gastro-enterology.

SECOND MEETING

Government Pavilion, Village, Tuesday, May 19,
8 p. m.

1. Chairman's Address: *Comments on Body Weight in Relation to Health and Disease*—Ernest S. du Bray, M. D., Flood Building, San Francisco.
Secretary's Report.
2. *Prognosis and Choice of Treatment in Graves' Disease*—J. Marion Read, M. D., 870 Market Street, San Francisco.

The natural clinical course has an important bearing on the treatment and prognosis of Graves' disease. The prognosis varies with age, sex, and the particular stage of the disease the patient is in when seen by the physician. The nervous make-up of the patient is an important factor, especially in the more chronic types. An attempt to properly evaluate in each case the various factors concerned in producing and maintaining this disease state should yield more satisfactory therapeutic results. About 2 per cent of patients who have this disease will succumb. These are mostly the acute, fulminating cases. Prognosis in the remainder of the acute cases is favorable for recovery. The chronic cases, which constitute about one-half of those seen, offer more difficulty from a therapeutic standpoint, and the prognosis for permanent cure is unfavorable.

3. *The Diabetic at Home*—Howard F. West, M. D., 1032 West Eighteenth Street, Los Angeles.

A discussion of some of the problems met with in an effort to keep the diabetic patient under control

and to aid him in realizing the health promised by modern methods after he leaves the hospital and the first intensive study. Illustrative cases showing the various sources of difficulties and some suggestions for their solution.

4. *The Clinical Significance of Bundle Branch Lesions*—Arthur Stanley Granger, M. D., 2007 Orange Street, Los Angeles.

Introduction: Pathology of these lesions. Mechanism of production of the very interesting electrocardiographic findings in the so-called bundle branch lesions. Symptoms and clinical signs in a group of thirty-five cases. Importance of demonstrating this condition, particularly from the standpoint of prognosis. Electro-cardiograms illustrating the typical findings, with a few case reports.

5. *A Clinical and Surgical Check on Liver Function Tests*—John V. Barrow, M. D., Westlake Professional Building, Los Angeles; William H. Olds, M. D., 607 South Hill Street, Los Angeles; Eugene L. Armstrong, M. D., 2005 Orange Street, Los Angeles.

1. The tests in every-day laboratory use; their technic and usability by the general profession.
2. What is shown in the normal individual under changes of physiologic conditions, as starvation, full stomach, fatty diet, starchy diet, and other conditions.
3. Application to clinical cases with reports.
4. Relative value of each test. 5. Conclusions.

THIRD MEETING

Government Pavilion, Village, Thursday, May 21,
2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *The Value of the Salivary Index as a Practical Office Procedure*—Clair L. Stealy, M. D., 415 Elm Street, San Diego.
1. Method of obtaining saliva, technique of test and salivary index (Hench and Aldrich). 2. Comparison of salivary urea by use of index with blood urea. 3. Type of cases used in, with findings. 4. Kidney function estimation by use of salivary urea, blood urea, urinary urea and phenolphthalein test. Summary of value.
3. *The Diagnosis of Chronic Amebiasis*—W. T. Davidson, M. D., 350 Post Street, San Francisco.
1. Prevalence in California. Soldiers returned from World War. Former residents of tropical and sub-tropical regions. Indigenous. 2. Diagnosis. Clinical symptoms. Typical cases. Series examination of stools following treatment, an important feature frequently overlooked in previous handling of case. Technic of these examinations. A typical case. Metastatic infections. Cytologic diagnosis. Specific organism; cysts.
4. *Therapeutics of Rest*—Allen H. Williams, M. D., 11 East Delaguerra Street, Santa Barbara.
5. *Pneumonic Plague*—Emil Bogen, M. D., 1100 Mission Road, Los Angeles; George Maner, M. D., 1100 Mission Road, Los Angeles.

Plague endemic in California. Recent epidemic of pneumonic form in Los Angeles emphasizes danger. Clinical diagnosis based upon history of exposure, high fever, severe prostration, diffuse bronchopneumonia, bloody sputum, and glandular enlargements. Laboratory aids by sputum smear, gland aspiration, guinea pig inoculation, and post-mortem findings. Therapy unsatisfactory. Prognosis poor. Prevention essential.

6. *Medical Management of Trophic Changes Incident to Vascular Disease*—J. Edward Harbinson, M. D., Woodland.

1. Selected cases of trophic changes, including gangrene, complicating endarteritis and other types of vascular disease can be treated with success medically. 2. Treatment: (a) General treatment of underlying cause. (b) Supplemental treatment: elimination of infection, rest in bed, heliotherapy, massage, sodium citrate intravenously and by mouth. 3. Results are good if economically feasible. 4. Report of cases.

GENERAL SURGERY SECTION

WALLACE I. TERRY, M. D., Chairman,
380 Post Street, San Francisco.

C. T. STURGEON, M. D., Secretary,
1136 West Sixth Street, Los Angeles.

FIRST MEETING

Government Pavilion, Village, Monday, May 18,
8 p. m.

1. Chairman's Address and Secretary's Report.
2. *The Relationship of the Clinical Pathologist to Surgical Practice*—Verne C. Hunt, M. D., Mayo Clinic, Rochester, Minnesota.

A discussion of the present-day role of the clinical pathologist. A statistical presentation illustrating the necessity of co-operation between pathologist and surgeon. A consideration of the influence of the clinical pathologist in the exercise of surgical judgment. Method of determining operability and a guide for the magnitude justifiable of a proposed surgical procedure. A basis of relative prognosis.

3. *Prophylaxis in the Treatment of Wound Infections*—Karl F. Meyer, M. D., Hooper Foundation, San Francisco.

A brief presentation of the various methods which have recently been developed to combat wound infections. In particular, the following will be considered: Sterilization of skin, the use of antitoxins against anaerobic infections, bacteriophage treatment, local application of filtered cultures, chemotherapy with vuzin, rivanol, etc.

Discussion opened by A. S. Lobingier, M. D., 307 West Eighth Street, Los Angeles; L. W. Hotchkiss, M. D., San Marcos Building, Santa Barbara.

4. *Some Surgical Aspects of Tubercular Peritonitis*—Charles D. Lockwood, M. D., 295 Markham Place, Pasadena.

A brief review of the literature of this subject, with special reference to the sources of infection and the routes of invasion. The possibility of direct infection from ruptured mesenteric glands. Discussion of surgical treatment and results. The surgical treatment of this condition has made very little progress and is still very unsatisfactory. The possibility of improved results by other methods of treatment. Report of cases.

Discussion opened by H. Brunn, M. D., 380 Post Street, San Francisco; Homer C. Oatman, M. D., Watts Building, San Diego.

5. *A Brief Outline of the Cause and Treatment of Chronic Polyarthrititis* (Report of 104 Cases)—Rea Smith, M. D., 1136 West Sixth Street, Los Angeles.

The cause of chronic deforming polyarthrititis lies in the ileocecal coil. The joints are a constitutional expression of a local disease. Treatment which does not include perfect intestinal drainage is not rational. Perfect intestinal drainage followed by restoration of bacterial balance will arrest disease and affect symptomatic cure, after which orthopaedic procedures to restore joint mobility can be carried out without fear of lighting up joint inflammation.

Discussion opened by Ellis Jones, M. D., 1136 West Sixth Street, Los Angeles.

6. *Thyroiditis*—Henry H. Searls, M. D., 1308 Fifth Avenue, San Francisco.

Division into acute, subacute, and chronic thyroiditis. Discussion of these groups with regard to incidence, etiology, diagnosis, treatment, and prognosis. In the main, a detailed study of the possible etiology and the clinical picture of chronic diffuse thyroiditis, together with its relationship to and differentiation from hyperplasia of the thyroid gland. References

Discussion opened by C. G. Toland, M. D., 523 West Sixth Street, Los Angeles; E. I. Bartlett, M. D., 240 Stockton Street, San Francisco.

SECOND MEETING

Government Pavilion, Village, Tuesday, May 19,
2 p. m.

1. *The Value of Ventriculography in Localizing Brain*

Tumors—Carl W. Rand, M. D., 140 South Norton Street, Los Angeles.

Summary of writer's cases in which the ventricle study has been carried out. Value of the procedure (a) as confirming previous neurological findings; (b) in the absence of localizing signs; percentage of cases in which tumors were localized; failure of ventricle study due to errors in technique. Mortality.

Discussion opened by H. C. Naffziger, M. D., 380 Post Street, San Francisco; Edward B. Towne, M. D., Stanford University Medical School, San Francisco.

2. *Surgical Judgment*—Fred R. Fairchild, M. D., Woodland.

Surgical judgment sound only if based on detailed knowledge of every factor of each case. These facts can only be known by facts obtained from (a) complete history, (b) complete physical examination, (c) all essential laboratory data. Since disaster often follows surgical operations, based on poor judgment (which is usually lack of knowledge of facts that should have been obtained) it is submitted that some constituted authority should have the right to demand for review the records of any case. The purpose of this review would be to determine whether or not the patient's safety had been properly guarded.

Discussion opened by A. B. Cooke, M. D., Hollingsworth Building, Los Angeles; C. M. Fox, M. D., Electric Building, San Diego.

3. *Knee-joint Surgery*—Ellis W. Jones, M. D., 1136 West Sixth Street, Los Angeles.

The present status of surgery in relation to disabilities of the knee-joint presents a wider scope for more efficient treatment and favorable prognosis in the end-results in cases of deranges menisci, loose bodies, infectious arthritis secondary to trauma, monoarticular types of chronic hypertrophic arthritis and fractures involving the joint.

Discussion opened by W. I. Baldwin, M. D., 380 Post Street, San Francisco.

4. *Diaphragmatic Hernia*—Case Reports (Lantern Slides)—John Homer Woolsey, M. D., 135 Stockton Street, San Francisco.

Diaphragmatic hernia is not of rare occurrence. Discussion will be according to the three types—congenital, acquired and traumatic, with regard to cause, location, symptomatology, and treatment.

Discussion opened by H. Brunn, M. D., 380 Post Street, San Francisco; J. H. Breyer, M. D., Chamber of Commerce Building, Pasadena.

5. *The Surgical Treatment of Echinococcosis*—H. W. Mills, M. D., Chamber of Commerce Building, San Bernardino.

Paper a purely academical one. Justification of title Dévé's work on spontaneous cure by vomica of certain hydatid cysts of lung. Echinococcosis hydatidosis and echinococcosis bavaro-tyrolienne. Surgical treatment of hydatid cysts of liver, lung, kidney, spleen, brain, muscles and connective tissue, pelvis, and certain rare locations. Remarks on Finocchetto's trocar-aspirator.

Discussion opened by P. K. Gilman, M. D., 350 Post Street, San Francisco; C. C. Snyder, M. D., 44 South Marengo Avenue, Pasadena.

THIRD MEETING

Government Pavilion, Village, Wednesday, May 20,
2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.

2. *Myositis Ossificans Traumatica, With Special Reference to Exostoses Following Dislocations of the Elbow* (Lantern Slides)—Emmet E. Rixford, M. D., 1795 California Street, San Francisco.

Etiology: Clinical course and treatment, especially choice of time for operative removal.

3. *Prognosis of Treatment for Congenital Hypertrophic Stenosis*—Burns S. Chaffee, M. D., Maxwell Building, Long Beach.

Differentiation between the two types of pyloric obstruction, the "hypertrophic" and the "spasmodic," has caused confusion in the treatment of the former type. Early operations were accompanied with a

high mortality, as they were not adaptable to infant subjects. Today surgical treatment is standardized, and most excellent results are obtained. Ultra-conservatism not infrequently blocks the golden opportunity of saving the lives of infants.

Discussion opened by Guy Cochran, M. D., Pacific Electric Building, Los Angeles; Alanson Weeks, M. D., 380 Post Street, San Francisco.

4. *Cancer of the Colon*—Samuel Robinson, M. D., San Marcos Building, Santa Barbara.

A plea for the earlier recognition of tumors of the large bowel. Pathology and operability. Reduction in mortality should result from closer study of symptoms and the choice of such operative methods as may be consistent with the patient's condition and the experience and skill of the surgeon.

Discussion opened by J. H. Shepherd, M. D., Twohy Building, San Jose; H. H. Sherk, M. D., 268 South Grove Street, Pasadena.

5. *The Pre-operative Preparation and Surgical Treatment of Carcinoma of the Pancreas With Common Duct Obstruction*—Leo P. Bell, M. D., Woodland.

1. Discussion of the literature, its etiology, pathology, and occurrence. 2. Discussion of the pre-operative preparation in regard to the intravenous administration of sodium chloride, transfusions, administration of calcium, together with the increased clotting and nephrosis of all secretory, glandular tissue. 3. Discussion of the operative choice and technique of cholecystogastrostomy and cholecystoduodenostomy. 4. Presentation of cases and prognosis. 5. Discussion of liver regeneration during and following the relief of the obstructive jaundice.

Discussion opened by E. C. Moore, M. D., 511 South Bonnie Brae, Los Angeles; James Percy, M. D., 1030 South Alvarado Avenue, Los Angeles.

6. *Intestinal Obstruction (Review of Ninety-three Cases)*—Edmund Butler, M. D., Butler Building, San Francisco; G. D. Delprat, M. D., San Francisco Hospital, San Francisco.

Intestinal obstruction (a) age, (b) sex, (c) duration of symptoms, (d) symptoms as presented: 1, vomiting; 2, pain; 3, distention; 4, peristalsis; 5, fever; 6, non-prot. nitrogen of blood; 7, shock; 8, leucocytosis; (e) signs of peritonitis, (f) procedure, (g) post-operative complications, (h) time in hospital, (i) mortality.

Discussion opened by Walter L. Huggins, M. D., 523 West Sixth Street, Los Angeles; Thomas O. Burger, M. D., First National Bank Building, San Diego.

INDUSTRIAL MEDICINE AND SURGERY SECTION

PHILIP H. STEPHENS, M. D., Chairman,
Pacific Electric Building, Los Angeles.

PACKARD THURBER, M. D., Secretary,
906 Black Building, Los Angeles.

FIRST MEETING

Tent, Lodge, Monday, May 18, 2 p. m.

- Chairman's Address and Secretary's Report.
- Derangement of the Ankle-joint Following Fractures of the Lower End of the Tibia and Fibula* (Lantern Slides)—Lionel D. Prince, M. D., 870 Market Street, San Francisco.

The purpose of this paper is, firstly, to emphasize the importance of absolute reduction of fractures of the tibia and fibula above the ankle-joint where the proper weight-bearing alignment is destroyed; and secondly, to emphasize the operative correction in those cases where union has been permitted to take place without regard for the restoration of the proper weight-bearing alignment. The method of

conservative reduction is given and likewise the operative technique in those cases where mal-union is present.

3. *Industrial Hernia vs. Seminal Vesiculitis*—Miley B. Wesson, M. D., 870 Market Street, San Francisco.

A large proportion of people are born with a potential hernia, and many of these acquire a seminal vesiculitis. Following a strain, there is a flare-up of the infection, which manifests itself as a vasitis. The first subjective symptom is a pain in the groin which the patient too often attempts to sell to the insurance company as an industrial hernia. The literature of traumatic hernia, as well as seminal vesiculitis, has been reviewed. Forty new cases of vasitis, many of which were diagnosed as hernia, are briefly reported.

Discussion opened by Emmet Rixford, M. D., 1795 California Street, San Francisco; H. A. Rosenkranz, M. D., N. P. Story Building, Los Angeles.

4. *The Diagnosis of Lead Poisoning in Industrial Plants*—C. O. Sappington, 354 Grand Avenue, Oakland.

1. Introduction. (a) Importance of lead in manufacturing; as toxicological hazard. (b) Recent work on lead poisoning in United States, Harvard Lead Unit, Industrial Clinic at Massachusetts General Hospital, the work of Hamilton, Wright, Shie, and others. (c) Recent experience with lead poisoning in California. 2. Important considerations bearing on the diagnosis of lead poisoning. (a) All compounds dangerous. (b) Dangerous forms; dust and fumes. (c) Ports of entry to the body. (d) Dangerous amounts of lead. (e) The cumulative effect. (f) Personal idiosyncrasy. (g) Age and sex. 3. The diagnostic standards of the United States Public Health Service. 4. Controversial diagnostic points with suggestions for changes in technique. (a) The lead line on the gums. (b) Methods of staining for stippled red cells. (c) Examination of muscle groups. (d) Tests for lead in air, urine, and feces. Medico-legal aspects. (e) The distinction between lead absorption and lead poisoning. 5. Summary.

SECOND MEETING

Tent, Lodge, Tuesday, May 19, 8 p. m.

Open Meeting With the State Committee on Industrial Medical Practice

THIRD MEETING

Tent, Lodge, Thursday, May 21; 2 p. m.

- Election of Section Officers and Transaction of Other Section Business.
- Milkman's Foot, an Industrial Injury*—Floyd Thurber, Black Building, Los Angeles.

1. Introduction. (a) Occurs particularly to milk route men. (b) Caused by repeated jumping on and off wagon. 2. Frequency. (a) Not an uncommon injury. (b) Failure of many cases to report. 3. History. (a) Important to diagnosis. 4. Examination. (a) All ligaments about foot and ankle. (b) Muscles of foot and calf. 5. Diagnosis. (a) History. (b) Examination. 6. Treatment. (a) Relief of strain. (b) Temporary support until muscles and ligaments become stronger. (c) Importance of patient continuing work with proper support of injured tissues. 7. Prognosis.

3. *Industrial Liability for Cancer*—A. R. Kilgore, M. D., 391 Sutter Street, San Francisco; Curtis E. Smith, M. D., 391 Sutter Street, San Francisco.

1. Brief consideration of relation of injury to (a) tumor origin, (b) tumor growth and metastasis. 2. Tumors likely to arise or be accelerated by a single occupational injury. 3. Tumors likely to arise from repeated mechanical or chemical injury. 4. Standardization of evidence necessary to hold injury responsible for tumor origin. 5. Evidence necessary to hold injury responsible for acceleration of tumor growth. 6. Suggested standardization of pro-

cedure in selected types of injury to avoid industrial losses from tumors.

NEUROPSYCHIATRY SECTION

GLENN E. MYERS, M. D., Chairman,
Marsh-Strong Building, Los Angeles.

JOSEPH CATTON, M. D., Secretary,
209 Post Street, San Francisco.

FIRST MEETING

Sentinel Dining-room, Village, Monday, May 18,
2 p. m.

1. Chairman's Address and Secretary's Report.
2. *Tryparsamide in Late Neurosyphilis*—J. Ross Moore, M. D., 520 West Seventh Street, Los Angeles; Irwin C. Sutton, M. D., Taft Building, Hollywood, Los Angeles.
3. *Clinical Report of Twelve Cases of Spinal Cord Tumor, With Special Reference to Early Symptomatology*—Thomas J. Orbison, M. D., 2007 Wilshire Boulevard, Los Angeles.
4. *Results of X-ray Treatment of Tumors of the Brain and the Hypophysis*—E. B. Towne, M. D., Stanford Medical School, San Francisco.
5. *Effect of Radium on General Paralysis*—Aaron J. Rosanoff, M. D., Westlake Professional Building, Los Angeles.

SECOND MEETING

Sentinel Dining-room, Village, Tuesday, May 19,
8 p. m.

1. *The Endocrine Influence in Certain Psychoses*—Edward Huntington Williams, M. D., Pacific Mutual Building, Los Angeles.
2. *Tuberculosis from the Psychiatric Approach—A Report of an Analysis of Forty Cases in and Out of Tuberculosis Hospitals*—Anita M. Muhl, M. D., Commonwealth Building, San Diego.
3. *The Psychiatrist in the University*—Eva C. Reid, M. D., 909 Hyde Street, San Francisco.
4. *The Plea for a Saner Psychology in Explanation of Psychoneuroses*—Milton B. Lennon, M. D., 380 Post Street, San Francisco.

THIRD MEETING

Sentinel Dining-room, Village, Thursday, May 21,
2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *The Closure of Skull Defects*—Charles L. Tranter, M. D., 209 Post Street, San Francisco.
3. *Bladder Disturbances in Lesions of the Nervous System*—Leon Meyers, M. D., 815 South Hill Street, Los Angeles.
4. *A Clinical and Pathological Study of a Fourth Ventricle Tumor Causing Symptoms of Marked Dystonia*—Walter F. Schaller, M. D., 909 Hyde Street, San Francisco.
5. *A Case of Familial Hereditary Ataxia*—Dwight E. Shepardson, M. D., Lane Hospital, San Francisco; Howard C. Naffziger, M. D., 380 Post Street, San Francisco.

OBSTETRICS AND GYNECOLOGY SECTION

PETER O. SUNDIN, M. D., Chairman,
H. W. Hellman Building, Los Angeles.

JOHN W. SHERRICK, M. D., Secretary,
350 Twenty-ninth Street, Oakland.

FIRST MEETING

Pillsbury Pavilion, Lodge, Monday, May 18, 2 p. m.
Symposium on Eclampsia

1. Chairman's Address and Secretary's Report.

2. *Etiology of Eclampsia*—P. O. Sundin, M. D., H. W. Hellman Building, Los Angeles.
Discussion to be opened by G. C. McPheeters, 1021 Mattei Building, Fresno.

3. *Laboratory Aids in the Diagnosis and Control of Eclampsia*—H. A. Stephenson, M. D., 516 Sutter Street, San Francisco.

Eclampsia defined. The true nature of the disease is not definitely known. Clinical symptoms of the condition. Clinical findings in the disease. Known pathology. Difficulty in differential diagnosis. Brief mention of various procedures used in attempts at diagnosis. The relative value of these procedures. Treatment of eclampsia. Conclusions.

Discussion to be opened by H. M. Ross, M. D., 523 West Sixth Street, Los Angeles.

4. *Recurrent Toxemia*—Hans von Geldern, M. D., 516 Sutter Street, San Francisco.

This paper is a consideration of all of the clinic patients entering the Lane Hospital and out-patient women's clinic with a diagnosis of toxemia of pregnancy, with special reference to previous and subsequent pregnancies. Those cases with histories of recurrences are especially dealt with to bring out the serious nature of recurrences.

Discussion to be opened by F. C. Ainley, M. D., 1136 West Sixth Street, Los Angeles.

5. *The Conservative Treatment of Eclampsia*—Margaret Schulze, M. D., University of California Hospital, San Francisco.

Etiology of eclampsia as yet unknown. Old idea that immediate delivery is essential. Question whether in some cases trauma of operative delivery is not the immediate cause of death. Remarkable results of Stronganoff with his method of profound narcosis. Rotunda elimination treatment. Venesection method of Lichtenstein. Outline of treatment employed at University of California and discussions of results.

Discussion opened by E. N. Ewer, M. D., 251 Moss Avenue, Oakland.

6. *The Role of Cesarean Section in the Treatment of Eclampsia*—J. C. Irwin, M. D., Union Bank Building, Los Angeles.

Discussion opened by R. K. Smith, M. D., 391 Sutter Street, San Francisco.

SECOND MEETING

Pillsbury Pavilion, Lodge, Tuesday, May 19, 2 p. m.

Joint Meeting With Pediatricians Symposium on Birth Injuries

1. *Cranial and Intra-Cranial Injuries in the New-Born From the Standpoint of the Obstetrician*—F. M. Loomis, M. D., 350 Twenty-ninth Street, Oakland.
2. *Symptoms and Diagnosis in Infants—Clinical Significance in Later Years*—Ralph H. Kuhns, M. D., 135 Stockton Street, San Francisco.
3. *Surgical Management*—H. C. Naffziger, M. D., 380 Post Street, San Francisco.
4. *Mongolism in Twins*—Henry Dietrich, M. D., 1136 West Sixth Street, Los Angeles.

THIRD MEETING

Pillsbury Pavilion, Lodge, Thursday, May 21, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.

Symposium on Pelvic Relaxation and Prolapse

2. *Some Points in the Anatomy and Mechanics of the Pelvic Floor*—A. W. Meyer, M. D., Stanford University.

An evaluation of the role played in pelvic support by some of the constituents of the pelvic and urogenital diaphragms, with special reference to views in current textbooks and periodical literature.

Discussion opened by C. H. Weaver, M. D., 2007 Orange Street, Los Angeles.

3. *Predisposing Factors in Pelvic Relaxation and Pro-*

lapse—John Vruwink, M. D., 523 West Sixth Street, Los Angeles.

The etiology of pelvic relaxation depends, to a large extent, upon constitutional inferiority or debility. Births, however, give rise to enlargement of the genital hiatus, subinvolution, hyperextension of the ligaments and prolapse. Birth trauma depends upon various factors, but is more frequent after certain forms of delivery. Adequate ante-partum and post-partum care are prophylactic measures for prolapse.

4. *Benign Lesions of the Cervix in Association With Pelvic Relaxation and Prolapse*—Michael Creamer, M. D., 520 West Seventh Street, Los Angeles.

Discussion opened by A. V. Pettit, M. D., 1499 Sutter Street, San Francisco.

5. *The Problem of Partial Prolapse With Cystocele and Rectocele in Young Women*—Frank Lynch, M. D., University of California Hospital, San Francisco.

Discussion opened by W. Clifford McKee, M. D., 1136 West Sixth Street, Los Angeles.

6. *The Treatment of Procidentia*—Alfred B. Spalding, M. D., Lane Hospital, San Francisco.

The study of the proper treatment for pelvic prolapse has been made from a review of the histories of some 400 patients in the Women's Clinic of Stanford University. This group includes various degrees of cystocele, rectocele, and uterine prolapse. With lantern slides, it will be attempted to demonstrate the method used at Stanford for the past eight years. This consists of dissecting the pelvic fascia and overlapping the same according to the Neel-Rawls' technique for cystocele; the removal of the uterus in all cases of prolapse and the cone amputation of the cervix with Watkins Wertheim interposition operation on patients without prolapse; the wide dissection of the posterior vaginal wall and the elevation of the rectum according to the method described by the author three years ago for rectocele. Special effort will be made to describe the method used for the control of hemorrhage in vaginal hysterectomy. Finally, some comments on the various methods used for restoring pelvic floor relaxation. In general, the results have been good. There have been the fewest returns of pelvic prolapse and cystocele. The chief difficulty with pelvic prolapse has been found with the posterior segment. The former difficulties of post-operative hemorrhage have been practically eliminated by the present technique.

Discussion opened by J. A. Sperry, 275 Post Street, San Francisco.

PATHOLOGY AND BACTERIOLOGY SECTION

NEWTON EVANS, M. D., Chairman,
Loma Linda.

ROY W. HAMMACK, M. D., Secretary,
523 West Sixth Street, Los Angeles.

FIRST MEETING

Sentinel Lobby, Village, Monday, May 18, 2 p. m.

1. Chairman's Address and Secretary's Report.
2. *Mitotic Figures in Malignant Tumors as Affected by Time Before Fixation of Tissues*—Newton Evans, M. D., College of Medical Evangelists, Loma Linda.
3. *Rupture of the Heart Wall—Five Examples*—F. R. Nuzum, M. D., Santa Barbara Cottage Hospital, Santa Barbara; H. J. Hagen, M. D., Santa Barbara Cottage Hospital, Santa Barbara.
4. *The Pathology of Plague*—George D. Maner, M. D., 1100 Mission Road, Los Angeles; Lawrence Parsons, M. D., 1100 Mission Road, Los Angeles.
5. *Giant Cell Tumors Unconnected With Bone*—Lenore Campbell, M. D., College of Medical Evangelists, Loma Linda.

SECOND MEETING

Sentinel Lobby, Village, Tuesday, May 19, 8 p. m.

1. *The Effects of Insulin Treatment on Experimental Diabetes of Dogs*—E. F. F. Copp, M. D., Scripps Metabolic Clinic, La Jolla.
2. *Should the Schick Test be Abandoned?*—W. H. Kellogg, M. D., State Hygienic Laboratory, Berkeley.
3. *Observations on the Tuberculin Reaction*—A. M. Moody, M. D., St. Francis Hospital, San Francisco.
4. *Infectious Mononucleosis, With Report of Five Cases*—Hersel Butka, M. D., White Memorial Hospital, Los Angeles.
5. *A Statistical Study of 13,000 Wassermann Examinations Among Railway Employees*—W. T. Cummins, M. D., Southern Pacific Hospital, San Francisco.

THIRD MEETING

Sentinel Lobby, Thursday, May 21, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *Syringomyelia and Syringobulbia*—Charles E. Nixon, M. D., 870 Market Street, San Francisco.
3. *Epithelioma of Uterus in a Rabbit*—Norman N. Epstein, M. D., University of California Hospital, San Francisco.
4. *Osteosclerotic Anemia*—W. L. Miles, M. D., University of California Hospital, San Francisco.
5. *Osteosclerotic Pseudoleukaemia*—Glanville Y. Rusk, M. D., University of California Hospital, San Francisco.

PEDIATRICS SECTION

ROBERT E. RAMSAY, M. D., Chairman,
959 East Colorado Street, Pasadena.

C. D. SWEET, M. D., Secretary,
242 Moss Avenue, Oakland.

FIRST MEETING

Pillsbury Pavilion, Lodge, Monday, May 18, 8 p. m.

1. Chairman's Address: *Social Aspects of the Free Dispensary*—Robert E. Ramsey, M. D., 959 East Colorado Street, Pasadena.

The free dispensary exists to give medical attention to deserving poor people. Many who are not poor take advantage of the situation. This is an outrage both to the givers of money and to the physicians who give their services. A study is made of patients seeking admission to a dispensary for children. Standards for admission are suggested. The necessity for social investigation is indicated. Justice to donors and physicians requires that social investigation of all applicants be made. The deserving poor do not object to visits which confirm their statements. The undeserving are discovered and excluded.

Secretary's Report.

2. *Allergy in Childhood—Its Manifestations and Recognition*—George Piness, M. D., 1136 West Sixth Street, Los Angeles.
3. *Allergy in Childhood—Its Treatment*—Albert H. Rowe, M. D., 242 Moss Avenue, Oakland.
4. *Antrum Disease in Childhood—Its Recognition and Treatment—Report of Cases*—F. M. Shook, M. D., 1904 Franklin Street, Oakland.

SECOND MEETING

Pillsbury Pavilion, Lodge, Tuesday, May 19, 2 p. m.

Joint Meeting With Obstetricians Symposium on Birth Injuries

1. *Cranial and Intra-Cranial Injuries in the New-Born From the Standpoint of the Obstetrician*—F. M. Loomis, M. D., 350 Twenty-ninth Street, Oakland.
2. *Symptoms and Diagnosis in Infants—Clinical Signifi-*

cance in Later Years—Ralph H. Kuhns, M. D., 135 Stockton Street, San Francisco.

3. *Surgical Management*—H. C. Naffziger, M. D., 380 Post Street, San Francisco.
4. *Mongolism in Twins*—Henry Dietrich, M. D., 1136 West Sixth Street, Los Angeles.

THIRD MEETING

Pillsbury Pavilion, Lodge, Wednesday, May 20, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *The Importance of the Teaching of Nutrition in the Public Schools*—William M. Happ, M. D., 523 West Sixth Street, Los Angeles.

The prevalence of undernutrition in children of school age is well known, and the children of Los Angeles show no exception to the rule. A survey of a number of representative schools shows that over 15 per cent of the children in this city are more than 10 per cent underweight for their height and age. A much larger percentage are undernourished, who are not greatly underweight. Nutrition classes have been organized for the most markedly undernourished children in over 100 schools. In these classes, which meet daily, the children are taught the principles of proper diet, rest, health habits, etc. The results are very satisfactory, as improvement in nutrition is the rule. We feel that the school is the ideal place to teach nutrition to the children, the reasons for which, and the methods of organization of the work, are outlined in the paper.

3. *The Health Department—Its Relation to Child Welfare*—John J. Sippy, M. D., 129 South American Street, Stockton.
4. *The Significance and Treatment of Growth Deviations in Childhood*—C. L. Lowman, M. D., 2417 South Hope Street, Los Angeles.

The main points covered will be: Disturbed body posture, especially significant of antero-posterior deviations in relation to fatigue and disturbance of chest and abdominal functions; growth handicaps due to nerve loss from muscular overwork; significance of foot and leg deviations; relation to nervous states and future disability, especially in relation to back strain.

5. *Tuberculous Infection and Disease in Infancy and Childhood*—William Palmer Lucas, M. D., University of California Hospital, San Francisco.

RADIOLOGY SECTION

(Including Roentgenology and Radium Therapy)

RAY G. TAYLOR, M. D., Chairman,
302 South St. Andrews Place, Los Angeles.

ROBERT NEWELL, M. D., Secretary,
Lane Hospital, San Francisco.

FIRST MEETING

Sentinel Lobby, Village, Monday, May 18, 8 p. m.

1. Chairman's Address and Secretary's Report.
2. *X-ray and Radium Treatment of Uterine Tumors*—Frederick H. Rodenbaugh, M. D., 516 Sutter Street, San Francisco.

Classification of cases suitable for treatment. Technique and selection of suitable agent. End-results of radiation therapy on the uterus and adnexia. Economic values. Comparison with surgical and other methods of treatment.

Discussion opened by Frank W. Lynch, M. D., University of California Hospital, San Francisco; A. B. Spalding, M. D., Lane Hospital, San Francisco.

3. *General Consideration of the Treatment of Superficial Malignancies by Means of Radium and the X-ray*—Albert Soiland, M. D., 1407 South Hope Street, Los Angeles; William E. Costolow, M. D., 1407 South Hope Street, Los Angeles.

General remarks on technique. Comparison of the radiation treatment with methods of treatment used prior to the general acceptance of the radiation treatment.

4. *Treatment of Breast Cancer*—Rex Duncan, M. D., 1151 West Sixth Street, Los Angeles.

Brief discussion of the various methods with sta-

tistics. X-ray as an adjunct to surgery. Microscopical studies of the effect of x-ray in breast cancer. Clinical observations in fifty cases treated by combined radiation and surgery.

SECOND MEETING

Sentinel Lobby, Village, Tuesday, May 19, 2 p. m.

1. *X-ray Diagnosis of Inflammatory Conditions of the Thorax*—Lloyd Bryan, M. D., 135 Stockton Street, San Francisco.

Uses and limitations of the roentgen ray differentiating between (a) tuberculosis; (b) tumors; (c) inflammatory lesions. The value of lipiodol in (a) bronchiectasis; (b) abscess; (c) tumors. Lantern slide demonstration of typical lesions.

2. *The Necessity for the Close Co-operation of the Roentgenologist and the Clinician in the Diagnosis of Lung Pathology*—W. R. P. Clark, M. D., 516 Sutter Street, San Francisco.

Introductory remarks. X-ray diagnosis, clinical aspects and demonstration of cases.

3. *Technique of the X-ray Examination of Patients With Digestive Disorders—A Plea for Standardization With Reason Why*—M. P. Burnham, M. D., St. Francis Hospital; J. R. O'Neill, M. D., St. Francis Hospital, San Francisco.

History of development of examination. Statement of uses and value of fluoroscope and films, separately and combined. Routine to be followed and technique. Question of expenses. Danger of taking short-cuts. Importance of personal observation at operations of patients examined. Value of procedure both as to gastro-intestinal tract and biliary and pancreatic systems.

4. *Chronic Appendicitis*—Henry Snure, M. D., 1501 South Figueroa Street, Los Angeles. What is meant by the term "chronic appendicitis." Brief review of roentgen ray findings compared to x-ray findings. Value of various signs and technique. Case reports of clinical cases of chronic appendicitis shown by roentgen ray examination to be due to other conditions.

THIRD MEETING

Sentinel Lobby, Village, Wednesday, May 20, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *Congenital Anomalies of Bones From Roentgen Standpoint*—W. B. Bowman, M. D., Brockman Building, Los Angeles.

Congenital anomalies are a common cause of incorrect diagnosis of bone injuries, often being mistaken for fractures. Thorough knowledge of the various anomalies and supernumerary bones is essential in correctly interpreting roentgenograms. Differentiation between anomalies and bone injuries is an important factor, particularly in industrial work.

3. *Congenital Anomaly of the Rib Cage*—H. J. Ullmann, M. D., Cottage Hospital, Santa Barbara.

Case presenting cervical ribs, no twelfth ribs, but normal number of vertebrae.

TECHNICAL SPECIALTIES SECTION

RAY LYMAN WILBUR, M. D., Chairman,
Stanford University, Palo Alto.

JOHN C. WILSON, M. D., Secretary,
1136 West Sixth Street, Los Angeles.

MEETING

Pillsbury Studio, Village, Tuesday, May 19, 8 p. m.

1. Election of Section Officers and Transaction of Other Section Business.

California Association of Physiotherapists

MISS SUSAN ROEN, President,
2422 Palm Drive, Los Angeles.

MRS. ALINE BRUMMELKAMP, Secretary,
507 Central Building, Pasadena.

Joint Meeting of Technical Specialties Section With California Association of Physiotherapists

1. President's Address and Secretary's Report.
2. *Physiotherapy in Conjunction With Glandular Ther-*

apy—Hans Lisser, M. D., 380 Post Street, San Francisco.

Discussion opened by William J. Kerr, M. D., University of California Hospital, San Francisco.

3. *Progressive Physiotherapy Treatment in Knee-joint Injuries*—Alfred Roncovieri, M. D., 870 Market Street, San Francisco.

Discussion opened by James T. Watkins, M. D., 909 Hyde Street, San Francisco; S. N. Jacobs, M. D., 209 Post Street, San Francisco.

4. *The Asthenic Child*—William P. Lucas, M. D., University of California Hospital, San Francisco.

Discussion opened by Florence Holsclaw, M. D., 380 Post Street, San Francisco.

5. *The Abuses of Physiotherapy in Industrial Accident Work*—W. C. Adams, M. D., 1904 Franklin Street, Oakland.

Discussion opened by E. I. Bartlett, M. D., 240 Stockton Street, San Francisco; E. W. Cleary, M. D., 177 Post Street, San Francisco.

6. Business Meeting.

California Association of Medical Social Workers

MISS EDNA J. SHIRPSER, President,
Children's Hospital, San Francisco.

MRS. SOPHIE H. MERSING, Secretary.
Mt. Zion Hospital, San Francisco.

MEETING

Pillsbury Studio, Village, Wednesday, May 20, 8 p. m.

1. President's Address and Secretary's Report.
2. *Problems and Progress in the Care of Drug Addicts*—Louise B. Deal, M. D., 69 Fair Oaks Street, San Francisco.

1. Formation of the Anti-Narcotic Section of the City and County Federation of Women's Clubs. 2. Appointment of the committee. 3. Drawing up of the program. 4. Educational campaign. 5. Drug addiction as a disease; (a) mechanism; (b) symptoms; (c) drug addict personally. 6. Drug addiction as regarded by the laity. 7. The accidental or innocent addiction—disease sufferers. 8. What can the physician offer? Three things—futility of all. 9. Saylor-Crowley bill No. 272. Creation of hospital for addicts.

Discussion opened by Eva C. Reid, M. D., 909 Hyde Street, San Francisco.

3. *Medical Social Service in Industry*—Margaret Paisley, Standard Oil Company, Richmond.

Discussion opened by Margaret T. Kyne, Market Street Railway, San Francisco.

4. *Principles Governing Free Medical and Hospital Service*—N. N. Wood, M. D., 1100 Mission Road, Los Angeles.

Discussion opened by Alfred C. Reed, M. D., 380 Post Street, San Francisco.

5. *Social Diagnosis*—Open discussion led by Miss N. Florence Cummings, Stanford Clinic, San Francisco.

6. *Medical Social Workers' Place in Improving Conditions of Mentally Diseased Patients*—Edward W. Twitchell, M. D., 909 Hyde Street, San Francisco.

Discussion opened by Joseph Catton, M. D., 209 Post Street, San Francisco.

7. Business Meeting.

UROLOGY SECTION

FRANK S. DILLINGHAM, M. D., Chairman,
Merchants National Bank Building, Los Angeles.

MILEY B. WESSON, M. D., Secretary,
Flood Building, San Francisco.

FIRST MEETING

Antler's Club, Village, Monday, May 18, 8 p. m.

1. Chairman's Address: *Unusual Urological Lesions*—Frank S. Dillingham, M. D., Merchants National Bank Building, Los Angeles.

Brief reports of three cases of fracture of the penis, one of priapism, one of anaphylaxis, and four

of toxins from ascarides and oxyuris causing hematuria and albuminuria.

Discussion opened by Victor G. Vecki, M. D., 516 Sutter Street, San Francisco.

2. *Some Observations on Tuberculosis of the Kidney, With a Report of Interesting and Unusual Cases*—William E. Stevens, M. D., Flood Building, San Francisco.

Difficulties in diagnosis in the absence of tubercle bacilli in the urine or in the presence of tubercle bacilli and the absence of all clinical symptoms; roentgen ray diagnosis; the differential diagnosis of renal calculi and tuberculosis; putty kidney; renal tuberculosis in children; tuberculosis of the kidney during pregnancy; treatment in the presence of bilateral involvement; prognosis under surgical and non-surgical treatment.

Discussion opened by Nathan G. Hale, M. D., Capital National Bank Building, Sacramento.

3. *Some Experiences in Kidney Surgery*—H. A. Rosenkranz, M. D., W. P. Story Building, Los Angeles.

The incision of choice; intensive use of tonics in pre and post-operative treatment; the six-day pedicle clamp; prevention of fistula following nephrectomy of tuberculous kidney; avoidance of the five principal errors in technic; when removing a calculus, the severing of aberrant vessels that are probably responsible for stasis which causes infection that results in calculi; role of the teeth in kidney pathology; drainage and antisepsis of incision. Diagnosis of rarer conditions. A peculiar masked case of chronic multiple miliary abscesses surrounding pelvis requiring nephrectomy.

Discussion opened by G. W. Hartman, 999 Sutter Street, San Francisco.

4. *Bilateral Nephrolithiasis*—A. J. Scholl, M. D., Pacific Mutual Building, Los Angeles.

Conditions which determine the side to be first treated surgically; nephrectomy and later resection of one-half of remaining kidney; studies of urea retention directly after operation, during pregnancy, and two years after operation.

Discussion opened by Louis C. Jacobs, M. D., 870 Market Street, San Francisco.

5. *Treatment of Uncomplicated Acute Gonorrhea in the Female*—Harry W. Martin, M. D., Detwiler Building, Los Angeles.

Interpretation of title; former treatments unsatisfactory, as shown by large numbers of salpingectomies; douches, tampons, suppositories, vaginal painting, sprays; vaginal and urethral instillations of acriflavine and argyrol.

Discussion opened by Victor G. Vecki, M. D., 516 Sutter Street, San Francisco.

6. *Radiographic Diagnosis of Kidney Tumors*—L. R. Reynolds, M. D., 291 Geary Street, San Francisco.

Lantern slide demonstration of pyelograms and of the pathological specimens.

Discussion opened by Frank Hinman, M. D., 380 Post Street, San Francisco.

7. *The Mechanical Factors Involved in the Production of the Symptoms of Movable Kidney*—Charles P. Mathe, M. D., Phelan Building, San Francisco.

Occurrence of movable kidney; etiology, congenital predisposition, erect posture, peculiar body form, laxness and peculiar formation of renal fasciae, trauma; pathology; complications; symptomatology; diagnosis; treatment, non-operative and operative; results.

Discussion opened by P. A. Ferrier, M. D., Citizens Savings Bank Building, Pasadena.

SECOND MEETING

Antler's Club, Village, Tuesday, May 19, 2 p. m.

1. *Rupture of the Urethra—Value of an Early Diagnosis*—Louis C. Jacobs, M. D., Flood Building, San Francisco.

Frequency of occurrence; classifications; extravasated urine resulting from trauma and an infected urethra associated with stricture. Report of two

cases; etiology; pathology; symptomatology; and treatment.

Discussion opened by A. J. Scholl, M. D., Pacific Mutual Building, Los Angeles.

2. *Operative Treatment of Rupture of the Male Urethra*—Franklin Farman, M. D., 1501 South Grand Avenue, Los Angeles.

Report of two cases of extravasation of urine following rupture of the posterior male urethra. Discussion of the immediate methods of handling such cases, prognosis and course. Description of technic and results obtained in secondary plastic repair of extensive urethral perineal fistula.

Discussion opened by A. J. Scholl, M. D., Pacific Mutual Building, Los Angeles.

3. *Effects of Prostatic Obstruction Produced Experimentally*—James R. Dillon, M. D., 516 Sutter Street, San Francisco.

Study of the pathological changes produced in the prostate, bladder, and kidneys; blood urea estimates at different periods; description of technic; conclusions. (Lantern Slides.)

Discussion opened by R. L. Rigdon, M. D., 291 Geary Street, San Francisco; E. W. Beach, M. D., Plaza Building, Sacramento.

4. *Results Obtained by Modification of Young's Perineal Prostatectomy*—Frank Hinman, M. D., 380 Post Street, San Francisco.

Description of modification: reasons for changes: (1) to secure better preservation of the external sphincter and (2) to insure more thorough and complete enucleation. Detailed comparison of 100 cases with results previously reported as having been obtained by the classical method. (Lantern Slides.)

Discussion opened by R. L. Rigdon, M. D., 291 Geary Street, San Francisco; E. W. Beach, M. D., Plaza Building, Sacramento.

5. *Suprapubic Prostatectomy*—Verne C. Hunt, M. D., Mayo Clinic, Rochester, Minnesota.

A discussion of indications for prostatectomy and conditions under which the graded operation is the one of choice; advantages of the one-stage operation; factors of safety and ultimate results.

Discussion opened by R. L. Rigdon, M. D., 291 Geary Street, San Francisco; E. W. Beach, M. D., Plaza Building, Sacramento.

6. *Complications Following Prostatectomy*—J. C. Negley, M. D., Haas Building, Los Angeles.

Immediate complications, hemorrhage, shock, acute dilatation of the heart, pneumonia, uremia, pyelitis, residual urine, incomplete enucleation, calculi, persistent sinus, dribbling, contracture of bladder neck.

Discussion opened by R. L. Rigdon, M. D., 291 Geary Street, San Francisco; E. W. Beach, M. D., Plaza Building, Sacramento.

THIRD MEETING

Antler's Club, Village, Wednesday, May 20, 2 p. m.

1. Election of Section Officers and Transaction of Other Section Business.
2. *Surgical Drainage of Prostatic Abscess*—Nathan G. Hale, M. D., Capital National Bank Building, Sacramento.

Various methods used in treatment in the past; foci of infection; symptoms; indications for operation; technic of operation; results with reference to symptoms; rectal findings, endoscopic examination and microscopical appearance of prostatic secretion. (Lantern Slides.)

Discussion opened by Franklin Farman, M. D., 1500 South Grand Avenue, Los Angeles.

3. *A Technic for the Treatment of Urethral Caruncle*—Paul A. Ferrier, M. D., Citizens Bank Building, Pasadena.

Frequency of urethral caruncle; importance as a cause of nervous symptoms; etiology; pathology; common methods of treatment and their unfavorable

results; technic of a modification of Crenshaw's method; advantages; results. Demonstration of instruments.

Discussion opened by William E. Stevens, M. D., Flood Building, San Francisco.

4. *Chyluria*—A. A. Kutzmann, M. D., University of California Hospital, San Francisco.

Brief resume of the literature; etiology; pathology; clinical picture; diagnosis and treatment. Report of a case.

Discussion opened by J. C. Negley, M. D., Haas Building, Los Angeles.

5. *Urinary Tract Involvement of Poliomyelitis*—Henry A. R. Kreutzmann, M. D., 1195 Bush Street, San Francisco.

A discussion of nerve lesions of the bladder in general; a resume of the various theories of micturition; report of a case of infantile paralysis involving the bladder.

Discussion opened by C. P. Mathe, M. D., Phelan Building, San Francisco.

6. *Autonephrectomy—Report of Animal Experimentation in an Effort to Produce Enclosed Renal Lesions*—L. P. Player, M. D., 380 Post Street, San Francisco; F. H. Redewill, M. D., University of California Hospital, San Francisco.

Review of literature. Rabbit experimentation to determine production of enclosed renal lesions with tubercle bacilli, etc., through blood and lymph channels and by direct extension along the ureters; report of an unusual case of walled-off cortical and medullary parenchyma with patent ureter and pelvis of kidney. (Lantern Slides.)

Discussion opened by James R. Dillon, M. D., 516 Sutter Street, San Francisco.

7. *A Safe and Accurate Method of Removing Small Obstructions at the Vesical Orifice Under Observation With the High Frequency Electrode*—Martin Molony, M. D., 1056 Sutter Street, San Francisco.

This method requires accuracy of diagnosis and permits the removal of the exact tissue desired. It is simple, accurate, effective, and devoid of danger.

Discussion opened by Henry A. R. Kreutzmann, M. D., 1195 Bush Street, San Francisco.

ANNUAL MEETING OF THE WESTERN BRANCH OF THE AMERICAN UROLOGICAL ASSOCIATION

CHARLES P. MATHE, M. D., President,
Phelan Building, San Francisco.

GEORGE W. HARTMAN, M. D., Secretary,
999 Sutter Street, San Francisco.

Antler's Club, Village, Wednesday, May 20, 8 p. m.

1. *Carcinoma of Urachus—Report of Case and Review of Literature*—H. W. Howard, M. D., Portland, Oregon.
2. *The Treatment of the Ureter in the Surgery of Tumors of the Bladder*—Verne C. Hunt, M. D., Mayo Clinic, Rochester, Minnesota.

A discussion of the relation of tumors of the bladder and the ureters. The ultimate results in the ureter and kidney of the various methods of treating the ureter. Indications for choice of the several procedures and comparison of the relative value of such procedures based on ultimate results.

3. *The Bloodless Removal of Stones from the Ureter*—Charles S. Vivian, Phoenix, Arizona.

Consideration of the formation of stones in the ureter. Consideration of the methods employed for removal; consideration of stones which may be expected to be expelled spontaneously; those which require bloodless methods and those which require surgical removal. Presentation of slides illustrating various conditions. Summary and conclusion.

4. Election of Officers and Business Meeting.

Utah State Medical Association

SOL G. KAHN, Salt Lake City.....President
WILLIAM L. RICH, M. D., Salt Lake.....Secretary
J. U. GIESY, Kearns Building, Salt Lake City,
Associate Editor for Utah

BOVINE MEANS BULL

In their action on the Hammond amendment, the present legislature has given the *coup d'grace* to one of the cults in Utah, namely, the Abramsites. From current press accounts of the final few moments preceding the vote, they would appear to have been as full of humor as the Abrams method of diagnosis itself. This would indicate that the house enjoyed a sort of three-ring circus, before voting against the further untrammelled freedom of the bovinites.

Speaking of bovine, we are filled with speculation. There was Jenner, and we know what he did with the dairy maids of England and the cow-pox vesicles and pustules on the patient English milk cows' teats. Big pox and small pox. Is it possible that while the cows were inoculating the dairy girls with the latter, the maids may by any chance have returned the compliment with what in Jenner's day and before was known as the French disease? Can this be the source of "bovine syphilis"? We don't know. Like Tutankamen, the thing is buried in the past, and we never knowingly saw a syphilitic cow in our life.

Yet there is that word "bovine." *De mortuis nil nisi bonum*. And yet we wonder if by any chance Abrams may himself have been a humorist—if perchance he may have realized at times how closely "bovine" and "bull" are related. In the words of Hashimuro Togo, "it is to ask."

OUR OWN DOORSTEP

Damage suits against doctors, like any other phenomena of life, taken individually or collectively, have a cause. And in this age, when the bringing of such suits has come to be so largely a favorite variety of indoor sport with a certain class of both patient and attorney, it behooves the medical world to take stock of itself, in order to learn if perhaps something of that cause may not be found within its own ranks. As a matter of fact, it is within the ranks of the profession that such cause often really lies. The fault which so oftentimes acts as an inciting spark to the explosion of such a suit against one of our own number too often lies on our own doorstep as a particularly obnoxious sort of dirt. And the reason why this is true, is a reason as old as human nature itself.

It is so easy to criticize. Criticizing is almost as easy as making mistakes. Yet criticism should be justly deserved before it is voiced. And to criticize justly one should be in possession of all major as well as all contributing facts. Here lies the rub. How many medical men, before expressing an opin-

ion as to the work of some colleague, take time to fully investigate? I don't know the answer. Anyone who does may speak. Judging by results, however, the percentage is not large. Were it larger, there would be a dwindling number of suits.

I honestly believe that the average physician does always the best he may for his patient. Only a fool would not. Yet aside from that fact as applying to the doctor's individual prestige, I honestly believe that the average doctor is inspired for and toward his patient's welfare. And what cachet have I to say he is not? We who practice the medical art know how much may contribute to a failure or result, aside from the doctor's own work or advice—things the patient fails to either confess or take into consideration when suit is brought. But certainly all of us should take such things into consideration before we criticize another man's result. Ignorance may to a degree excuse the patient, but surely—surely, ignorance of such things can be no excuse for us, because such ignorance is not ours.

Recently it has been my pleasure to land such a suit in the ash-can, so to speak. The attending physician did his work cleanly, correctly, and the work was undone by a "visiting" nurse employed by an industrial concern who undertook to do her stuff. The industrial physician was stated by the patient to have said the medical man's work had been wrong. Yet the industrial physician made a mistake. The case was an instance of allergy, pure and simple, manifested through an application made to the patient's body by the nurse. Yet suit was quite possible in this instance. And suits hurt any of us, even though a decision favorable to us is the result.

Recently, too, it was my pleasure to refuse to testify in a case being brought. Here, after investigation, I informed the attorney for the plaintiff that my testimony would be inimical to his client's interests. The final judicial decision supported this contention. The plaintiff lost.

These instances are cited merely to point the moral of sweeping our own doorstep first. It's the old story of casting stones. So many of us, if we look into our own past, will find that we equally dwell in houses of glass. It's so easy to see the mote in the eye of our neighbor, but—haven't we maybe a flag pole or two in our own optics? The chances are that we have. Somebody with a sense of humor and a trace of philosophy in his make-up recently remarked that the Christian nations would thrive better when they began to practice Christianity. Something of the same thing applies to us. Why criticize one another? Why cast slurs or aspersions on another's work? And especially why do it to a layman, who will misunderstand and broadcast his misunderstanding far and wide to the injury not only of the one whom we have decried to him, but of our profession at large? Why in the name of common sense, common decency, commercial advantage, justice, fairness, even self-defense, cast stigmata—unless provenly deserved—upon any member of the profession which we have made ours?

Utah Notes (reported by J. U. Giesy, associate editor)
—As a result of recent elections in the component socie-

ties, the following members are now officers of those societies as follows:

Box Elder County—Richard A. Pearce, president; W. LeRoy Smith, secretary-treasurer.

Cache Valley County—Eugene Worley, president; G. L. Rees, secretary-treasurer.

Carbon County—R. E. Dowd, president; J. M. Simpkin, secretary-treasurer.

Uintah County—M. Garrett O'Donnell, president; Homer E. Rich, secretary.

Utah County—J. W. Hagen, president; Arnold Robinson, secretary.

Salt Lake County—John Z. Brown, president; M. M. Critchlow secretary.

Weber County—E. M. Conroy president; R. L. Draper, secretary-treasurer.

The following speakers have accepted the invitation of the state association to the annual meeting:

Dr. Carla Hamman, Surgery, Cleveland; Dr. Ernest Sachs, Neurological Surgery, St. Louis; Dr. W. F. Braasch, Genito-Urinary Diseases, Rochester, Minn.; Dr. Carman, X-ray, Rochester, Minn.; Dr. Eusterman, Internal Medicine, Rochester, Minn.; Dr. Martin Engman, Dermatology, St. Louis; Dr. W. C. Alvarez, Internal Medicine, San Francisco; Dr. G. D. Stewart, Surgery, New York City.

This is an indication of what the program will be and what those who attend the state meeting may expect to receive. The committee on program are to be congratulated on having secured such an exceptionally desirable list of speakers. Let every member who possibly can begin now to so lay his plans that he may attend.

Senate Bill No. 9, after a somewhat uncertain gestation in the course of which it at one time seemingly died, only to be later revived, finally became a stillborn product of legislative conception in the closing hours of the legislature. The enacting clause was stricken in the house. For this the general public, whether aware of the fact at present or not, should give the lower body of the legislature their sincere thanks. Bill No. 9 was the pet measure of the chiro, which would have enabled them to treat industrial accident cases, under Commission control. While medically speaking, the enactment of such a measure would perhaps have resulted in no more than a demonstration of the effects such methods of treatment applied to traumatic injuries might be expected to produce, yet one wonders just what those results might have proved in the case of a traumatic spine, for example, as affecting the individual case. Viewed in that light, it is unlikely that the fate of Senate Bill No. 9 will cause any member of the medical profession to weep.

Salt Lake County Medical Society (reported by L. J. St. Paul, acting secretary)—The meeting held February 23 was called to order by President John Z. Brown. Members present, twenty-two; visitors, two.

W. R. Calderwood read a paper on "Causes and Methods of Prevention of Apoplexy." His data were taken from his own practice, in connection with insurance records to which he has access. He emphasized the importance of toxemia in the G. I. tract, and of stimulants, such as alcohol, coffee, and tea, as important causes.

T. F. H. Morton read a paper on the "Treatment of Climacteric Symptoms." He emphasized the importance of surgical removal of all foci of infection in the region of the cervix peritoneum and pelvic cavities, as well as glandular therapy. These papers were discussed by T. C. Gibson, Sol G. Kahn, and G. H. Pace.

The application of C. H. Hobbs was read and referred to the board of censors. Sol G. Kahn, chairman of the Committee on Public Health and Legislation, reported on the activities of the state legislature to date, so far as that related to the profession.

The regular meeting of March 9 (reported by M. M. Critchlow, secretary) was called to order by President John Z. Brown, forty-five members and one visitor being present.

The scientific program was arranged by the Ophthal-

mological Society. F. Leaver Stauffer read a paper on "Paranasal Sinus Disease in Children." He emphasized the frequency of this condition, discussed the etiological factors, anatomy of the sinus, symptoms, complications, diagnosis, and treatments. E. M. Neher read an instructive paper on "Ocular Headaches and Their Diagnosis," and described the anatomy and physiology of the eye and fifth cranial nerve. He discussed the differential diagnosis of headaches and described the treatment. W. D. Donohoe presented the subject of "General Practitioner and Specialist." He emphasized the harm that may be done to a patient by improper operations about the eye, ear, nose and throat, and discussed the proper method of moving foreign bodies from the cornea and the necessity of accurate diagnosis for eye conditions before treatment is adopted. He deprecated the fact that much unnecessary surgery of the nose and throat is done, and described what should be the limitations of the dentist's field. He stressed the clean and complete removal of tonsils only when such an operation is indicated. These papers were discussed by L. W. Snow and A. L. Brown.

President Brown suggested that the society have a committee to supervise public lectures, the function of which would be to provide speakers from the society for health talks, at the request of lay institutions, to pass upon outside speakers giving public lectures of health and to supervise weekly health talks over the radio. Discussed by F. H. Raley and W. G. Schulte. M. M. Critchlow moved that a committee to supervise public lectures consisting of three members be appointed. Discussed by T. F. H. Morton. Seconded and carried.

The application for membership of C. H. Hobbs was voted upon and he was unanimously elected to membership, thirty-five members voting.

Nevada State Medical Association

W. M. EDWARDS, M. D., Mason.....President
CLAUDE E. PIERSALL, M. D., Reno.....
Secretary-Treasurer and Associate Editor for Nevada

Washoe County Medical Society (reported by Henry Albert, secretary)—The Washoe County Medical Society met in regular session in the rooms of the Chamber of Commerce March 10, President Vinton A. Muller presiding.

The minutes of the previous meetings of February 9 and February 13, 1925, were read and approved.

C. E. Piersall read a paper on "Ultra-Violet Therapy." He discussed the diseases in which actinic rays are especially helpful and the advantages of artificial light over sunlight.

Clain Fanning Gelston of San Francisco presented a paper on "Lipoidal Injections With Radiology of the Bronchial Tree in Children." The material injected is a vegetable oil, to which a certain amount of iodine has been added. Its value in localizing pathological processes and as a guide to treatment, especially surgical, was discussed. The paper was illustrated with lantern slides, and was discussed by Robinson, Morrison, Bath, and Piersall.

V. A. Muller demonstrated a stomach tube which was used at Nevada City, Calif., in September, 1856, to empty the stomach of John Wilkes Booth after he had been on a drinking spree.

The automatic syringe was rather elaborate in its construction.

On motion, the society was instructed to negotiate with Dr. J. LaRue Robinson with regards to the purchasing of the projection lantern which he had kindly permitted the society to use during the past year. Dr. Robinson thereupon announced that he presented the lantern to the society. The president thanked Dr. Robinson on behalf of the society, and instructed the secretary to take charge of the lantern.

Attendance—Members: Albert, Barrows, Bath, Caples, DaCosta, Fuller, Morrison, Muller, Richardson, Piersall, Robinson, Servoss, Stadtherr, and West.

Medical Economics and Public Health

Nationalize! Centralize! These seem to be the slogans of individuals who do not understand what the fundamental American system is, and who would like to change our system after a foreign pattern. Why, we fought the Revolution to escape a concentration of power unwisely used. Our forefathers were determined that they would make no such mistakes in America. Power was to be wisely distributed and jealously guarded.—United States Senator Overman.
